-- and a particular solution (for a given regime)
-- Rec2 stores the rank, and a list of subdeterminants of that rank,
-- and a Groebner basis for the ideal they generate.
-- Rec3 stores a regime and the corresponding solution; the regime is
-- given by a list of equations (eqzro) and one inequation (neqzro)
-- describing the quasi-algebraic set which is the regime; the
-- additional consistency conditions due to the rhs is given by wcond.
-- Ranksolns stores a list of regimes and their solutions, and the number
-- of regimes all together.
-- Rec8 (temporary) stores a quasi-algebraic set with an indication
-- whether it is empty (sysok = false) or not (sysok = true).

-- I think psolve should be renamed parametricSolve, or even
-- parametricLinearSolve. On the other hand, may be just solve will do.
-- Please feel free to change it to conform with system conventions.
-- Most psolve routines return a list of regimes and solutions,
-- except those that output to file when the number of regimes is
-- returned instead.
-- This version has been tested on the pc version 1.608 March 13, 1992

-- this is mode 11

wrregime : (L Rec3, S) -> I
++ wrregime(l,s) writes a list of regimes to a file named s
++ and returns the number of regimes written

rdregime : S -> L Rec3
++ rdregime(s) reads in a list from a file with name s

bsolve: (M GR, LGF, NNI, S, Inputmode) -> RankSolsns
++ bsolve(c, w, r, s, m) returns a list of regimes and
++ solutions of the system c z = w for ranks at least r;
++ depending on the mode m chosen, it writes the output to
++ a file given by the string s.

dmp2rfi: GR -> GF
++ dmp2rfi(p) converts p to target domain

dmp2rfi: M GR -> M GF
++ dmp2rfi(m) converts m to target domain

dmp2rfi: L GR -> L GF
++ dmp2rfi(l) converts l to target domain

se2rfi: L Symbol -> L GF
++ se2rfi(l) converts l to target domain

pr2dmp: PR -> GR
++ pr2dmp(p) converts p to target domain

hasoln: (Fgb, L GR) -> Rec8
++ hasoln(g, l) tests whether the quasi-algebraic set
++ defined by p = 0 for p in g and q ^= 0 for q in l
++ is empty or not and returns a simplified definition
++ of the quasi-algebraic set
-- this is now done in QALGSET package

ParCondList: (M GR, NNI) -> RankConds
++ ParCondList(c,r) computes a list of subdeterminants of each
++ rank >= r of the matrix c and returns
++ a groebner basis for the
++ ideal they generate

redpps: (Linsoln, Fgb) -> Linsoln
++ redpps(s,g) returns the simplified form of s after reducing
++ modulo a groebner basis g

-- LOCAL FUNCTIONS

B1solve: Linsys -> Linsoln
++ B1solve(s) solves the system (s.mat) z = s.vec
++ for the variables given by the column indices of s.cols
++ in terms of the other variables and the right hand side s.vec
++ by assuming that the rank is s.rank,
++ that the system is consistent, with the linearly
++ independent equations indexed by the given row indices s.rows;
++ the coefficients in s.mat involving parameters are treated as
++ polynomials. B1solve(s) returns a particular solution to the
++ system and a basis of the homogeneous system (s.mat) z = 0.
factorset: GR -> L GR
++ factorset(p) returns the set of irreducible factors of p.
maxrank: RankConds -> NNI
++ maxrank(r) returns the maximum rank in the list r of regimes
minrank: RankConds -> NNI
++ minrank(r) returns the minimum rank in the list r of regimes
minset: L L GR -> L L GR
++ minset(sl) returns the sublist of sl consisting of the minimal
++ lists (with respect to inclusion) in the list sl of lists
nextSublist: (I, I) -> L L I
++ nextSublist(n,k) returns a list of k-subsets of {1, ..., n}.
overset?: (L GR, L L GR) -> Boolean
++ overset?(s,sl) returns true if s properly a sublist of a member
++ of sl; otherwise it returns false
ParCond : (M GR,NNI) -> Eqns
++ ParCond(m,k) returns the list of all k by k subdeterminants in
++ the matrix m
redmat: (M GR, Fgb) -> M GR
++ redmat(m,g) returns a matrix whose entries are those of m
++ modulo the ideal generated by the groebner basis g
regime: (Rec,M GR,L GF,L L GR,NNI,NNI,Inputmode) -> Rec3
++ regime(y,c, w, p, r, rm, m) returns a regime,
++ a list of polynomials specifying the consistency conditions,
++ a particular solution and basis representing the general
++ solution of the parametric linear system c z = w
++ on that regime. The regime returned depends on
++ the subdeterminant y.det and the row and column indices.
++ The solutions are simplified using the assumption that
++ the system has rank r and maximum rank rm. The list p
++ represents a list of list of factors of polynomials in
++ a groebner basis of the ideal generated by higher order
++ subdeterminants, and ius used for the simplification.
++ The mode m
++ distinguishes the cases when the system is homogeneous,
++ or the right hand side is arbitrary, or when there is no
++ new right hand side variables.

sqfree: GR -> GR
++ sqfree(p) returns the product of square free factors of p

inconsistent?: L GR -> Boolean
++ inconsistent?(pl) returns true if the system of equations
++ p = 0 for p in pl is inconsistent. It is assumed
++ that pl is a groebner basis.
-- this is needed because of change to
-- EuclideanGroebnerBasisPackage

inconsistent?: L PR -> Boolean
++ inconsistent?(pl) returns true if the system of equations
++ p = 0 for p in pl is inconsistent. It is assumed
++ that pl is a groebner basis.
-- this is needed because of change to
-- EuclideanGroebnerBasisPackage

The package PartialFractionPackage gives an easier to use interface to the domain PartialFraction. The user gives a fraction of polynomials, and a variable and the package converts it to the proper datatype for the PartialFraction domain.

When Axiom is given an expression such as:

\[ a := \frac{x+1}{y+1} \]

it will end up with the result in Fraction Polynomial Integer.

\[ x \cdot y + x + 1 \]
\[ \frac{------------}{y + 1} \]

We might want it in a partial fraction form. This can be done with:

\[
\text{partialFraction}(a, y) \text{PFRPAC(INT)}
\]

\[
1 \\
\frac{x + \text{----}}{y + 1}
\]

We can do the same thing with a different variable:

\[
b := \frac{y+1}{x+1} \]

\[
(x + 1)y + 1 \\
\frac{------------}{x + 1}
\]

\[
\text{partialFraction}(b, x) \text{PFRPAC(INT)}
\]

\[
1 \\
\frac{y + \text{----}}{x + 1}
\]

++ Author: William H. Burge
++ Date Created: 29 October 1987
++ Date Last Updated: 3 April 1991
++ Description:
++ PartitionsAndPermutations contains functions for generating streams of
++ integer partitions, and streams of sequences of integers
++ composed from a multi-set.

PartitionsAndPermutations: Exports == Implementation where
  I ==> Integer
  L ==> List
  ST ==> Stream
  ST1 ==> StreamFunctions1
  ST2 ==> StreamFunctions2
  ST3 ==> StreamFunctions3

Exports ==> with

  partitions: (I,I,I) -> ST L I
  \spad{partitions(p,l,n)} is the stream of partitions
  ++ of n whose number of parts is no greater than p
  ++ and whose largest part is no greater than l.

  partitions: I -> ST L I
  \spad{partitions(n)} is the stream of all partitions of n.

  partitions: (I,I) -> ST L I
  \spad{partitions(p,l)} is the stream of all
  ++ partitions whose number of
  ++ parts and largest part are no greater than p and l.

  conjugate: L I -> L I
  \spad{conjugate(pt)} is the conjugate of the partition pt.

  conjugates: ST L I -> ST L I
  \spad{conjugates(lp)} is the stream of conjugates of a stream
  ++ of partitions lp.

  shuffle: (L I,L I) -> ST L I
  \spad{shuffle(l1,l2)} forms the stream of all shuffles of l1
  ++ and l2, i.e. all sequences that can be formed from
  ++ merging l1 and l2.

  shufflein: (L I,ST L I) -> ST L I
  \spad{shufflein(l,sl)} maps shuffle(l,u) on to all
  ++ members u of sl, concatenating the results.

  sequences: (L I,L I) -> ST L I
  \spad{sequences(l1,l2)} is the stream of all sequences that
  ++ can be composed from the multiset defined from
  ++ two lists of integers l1 and l2.
  ++ For example, the pair \spad{([1,2,4],[2,3,5])} represents
  ++ multi-set with 1 \spad{1’s}, 2 \spad{2’s}, and 4 \spad{5’s}.

  sequences: L I -> ST L I
  \spad{sequences(l)} is the set of
  ++ all sequences formed from
  ++ \spad{10} 0’s, \spad{11} 1’s, \spad{12} 2’s, \ldots, \spad{ln} n’s.

  permutations: I -> ST L I
  \spad{permutations(n)} is the stream of permutations
  ++ formed from \spad{1,2,3,\ldots,n}.

)abbrev package PMASS PatternMatchAssertions
++ Author: Manuel Bronstein
++ Date Created: 21 Mar 1989
++ Date Last Updated: 23 May 1990
++ Description:
++ Attaching assertions to symbols for pattern matching.

PatternMatchAssertions(): Exports == Implementation where
FE => Expression Integer

Exports => with
assert : (Symbol, String) -> FE
++ assert(x, s) makes the assertion s about x.
constant: Symbol -> FE
++ constant(x) tells the pattern matcher that x should
++ match only the symbol 'x and no other quantity.
optional: Symbol -> FE
++ optional(x) tells the pattern matcher that x can match
++ an identity (0 in a sum, 1 in a product or exponentiation).
multiple: Symbol -> FE
++ multiple(x) tells the pattern matcher that x should
++ preferably match a multi-term quantity in a sum or product.
++ For matching on lists, multiple(x) tells the pattern matcher
++ that x should match a list instead of an element of a list.

Implementation ==> add
import FunctionSpaceAssertions(Integer, FE)

constant x == constant(x::FE)
multiple x == multiple(x::FE)
optional x == optional(x::FE)
assert(x, s) == assert(x::FE, s)

— package INTPM PatternMatchIntegration —

PatternMatchIntegration (INTPM)

Exports:
  pmComplexintegrate pmintegrate pmintegrate splitConstant

)abbrev package INTPM PatternMatchIntegration
++ Author: Manuel Bronstein
++ Date Created: 5 May 1992
++ Date Last Updated: 27 September 1995
++ Description:
  ++ \spadtype{PatternMatchIntegration} provides functions that use
  ++ the pattern matcher to find some indefinite and definite integrals
  ++ involving special functions and found in the litterature.

PatternMatchIntegration(R, F): Exports == Implementation where
R : Join(OrderedSet, RetractableTo Integer, GcdDomain,
   LinearlyExplicitRingOver Integer)
F : Join(AlgebraicallyClosedField, TranscendentalFunctionCategory,
   FunctionSpace R)
N ==> NonNegativeInteger
Z ==> Integer
SY ==> Symbol
K ==> Kernel F
P ==> SparseMultivariatePolynomial(R, K)
SUP ==> SparseUnivariatePolynomial F
PAT ==> Pattern Z
RES ==> PatternMatchResult(Z, F)
OFE ==> OrderedCompletion F
REC ==> Record(which: Z, exponent: F, coeff: F)
ANS ==> Record(special:F, integrand:F)
NONE ==> 0
EI ==> 1
ERF ==> 2
SI ==> 3
CI ==> 4
GAM2 ==> 5
CI0 ==> 6

Exports ==> with
   splitConstant: (F, SY) -> Record(const:F, nconst:F)
      ++ splitConstant(f, x) returns \spad{\[c, g\]} such that
      ++ \spad{f = c * g} and \spad{c} does not involve \spad{t}.
   if R has ConvertibleTo Pattern Integer and
   R has PatternMatchable Integer then
      if F has LiouvillianFunctionCategory then
         pmComplexintegrate: (F, SY) -> Union(ANS, "failed")
            ++ pmComplexintegrate(f, x) returns either "failed" or
            ++ \spad{\[g, h\]} such that
            ++ \spad{integrate(f, x) = g + integrate(h, x)}.
            ++ It only looks for special complex integrals that pmintegrate
            ++ does not return.
      pmintegrate: (F, SY) -> Union(ANS, "failed")
         ++ pmintegrate(f, x) returns either "failed" or \spad{\[g, h\]} such
         ++ that \spad{integrate(f, x) = g + integrate(h, x)}.
   if F has SpecialFunctionCategory then
      pmintegrate: (F, SY, OFE, OFE) -> Union(F, "failed")
         ++ pmintegrate(f, x = a..b) returns the integral of
         ++ \spad{\[f(x)dx\}} from a to b
         ++ if it can be found by the built-in pattern matching rules.

--S 3 of 3
The package Permanent provides the function permanent for square matrices. The permanent of a square matrix can be computed in the same way as the determinant by expansion of minors except that for the permanent the sign for each element is 1, rather than being 1 if the row plus column indices is positive and -1 otherwise. This function is much more difficult to compute efficiently than the determinant. An example of the use of permanent is the calculation of the n-th derangement number, defined to be the number of different possibilities for n couples to dance but never with their own spouse.

Consider an n by n matrix with entries 0 on the diagonal and 1 elsewhere. Think of the rows as one-half of each couple (for example, the males) and the columns the other half. The permanent of such a matrix gives the desired derangement number.

```lisp
kn n ==
  r : MATRIX INT := new(n,n,1)
  for i in 1..n repeat
    r.i.i := 0
  r
```

Here are some derangement numbers, which you see grow quite fast.

```lisp
permanent(kn(5) :: SQMATRIX(5,INT))
```

[permanent(kn(n) :: SQMATRIX(n,INT)) for n in 1..13]

)abbrev package PERMAN Permanent
++ Authors: Johannes Grabmeier, Oswald Gschnitzer
++ Date Created: 7 August 1989
++ Date Last Updated: 23 August 1990
++ References:
  ++ Henryk Minc: Evaluation of Permanents,
  ++ Nijenhuis and Wilf : Combinatorial Algorithms, Academic
  ++ S.G.Williamson, Combinatorics for Computer Science,
++ Description:
  ++ Permanent implements the functions permanent, the
  ++ permanent for square matrices.

Permanent(n : PositiveInteger, R : Ring with commutative("*")):
public == private where
  I ==> Integer
  L ==> List
  V ==> Vector
  SM ==> SquareMatrix(n,R)
```
public => with

permanent: SM -> R
  + permanent(x) computes the permanent of a square matrix x.
  + The permanent is equivalent to
  + the \spadfun{determinant} except that coefficients have
  + no change of sign. This function
  + is much more difficult to compute than the
  + determinant. The formula used is by H.J. Ryser,
  + improved by [Nijenhuis and Wilf, Ch. 19].
  + Note that permanent(x) choose one of three algorithms, depending
  + on the underlying ring R and on n, the number of rows (and
  + columns) of x:
  + if 2 has an inverse in R we can use the algorithm of
  + [Nijenhuis and Wilf, ch.19,p.158]; if 2 has no inverse,
  + some modifications are necessary:
  + if n > 6 and R is an integral domain with characteristic
  + different from 2 (the algorithm works if and only 2 is not a
  + zero-divisor of R and characteristic()$\neq 2,
  + but how to check that for any given R ?),
  + the local function permanent2 is called:
  + (works for all commutative rings R).

  ++ janko2(li) constructs the janko group acting on the 100
  ++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 100 different entries

janko2: () -> PERMGRP I
++ janko2 constructs the janko group acting on the
++ integers 1, ..., 100.

rubiksGroup: () -> PERMGRP I
++ rubiksGroup constructs the permutation group representing
++ Rubik’s Cube acting on integers 10*i + j for
++ 1 <= i <= 6, 1 <= j <= 8.
++ The faces of Rubik's Cube are labelled in the obvious way
++ Front, Right, Up, Down, Left, Back and numbered from 1 to 6
++ in this given ordering, the pieces on each face
++ (except the unmoveable center piece) are clockwise numbered
++ from 1 to 8 starting with the piece in the upper left
++ corner. The moves of the cube are represented as permutations
++ on these pieces, represented as a two digit
++ integer ij where i is the number of the face (1 to 6)
++ and j is the number of the piece on this face.
++ The remaining ambiguities are resolved by looking
++ at the 6 generators, which represent a 90 degree turns of the
++ faces, or from the following pictorial description.
++ Permutation group representing Rubik’s Cube acting on integers
++ 10*i + j for 1 <= i <= 6, 1 <= j <= 8.
++ \begin{verbatim}

++ Rubik’s Cube: +-----+ +-- B
++ / U /|/
++ / / | F(ront) <-> 1
++ L --> +-----+ R(ight) <-> 2
++ | | + U(p) <-> 3
++ | F | / D(own) <-> 4
++ | |/ L(eft) <-> 5
++ +-----+ B(ack) <-> 6
++ ^
++ |
++ D
++
++ The Cube’s surface:
++ The pieces on each side
++ |567| (except the unmoveable center
++ |408| piece) are clockwise numbered
++ |321| from 1 to 8 starting with the
++ |781|123|345| piece in the upper left
++ |6L2|8F4|2R6| corner (see figure on the
++ |543|765|187| left). The moves of the cube
++ +-----+---+---++---+---+---+
++ |123|408|321|781|123|408|321|781|
++ |8D4|543|6L2|543|6L2|543|6L2|543|

PolyGroebner examples
====================================================================
This package is an interface package to the groebner basis package which allows you to compute groebner bases for polynomials in either lexicographic ordering or total degree ordering refined by reverse lex. The input is the ordinary polynomial type which is internally converted to a type with the required ordering. The resulting groebner basis is converted back to ordinary polynomials. The ordering among the variables is controlled by an explicit list of variables which is passed as a second argument. The coefficient domain is allowed to be any gcd domain, but the groebner basis is computed as if the polynomials were over a field.

The simple Euclidean division algorithm,
given $a \neq 0$, $b \neq 0$ where $a$ and $b$ are two polynomials in the variable $x$, then
output $q$, the quotient and $r$, the remainder

begin
Let
$q = 0$
$r = a$
$d = \text{degree}(b)$
$c = \text{leadingCoefficient}(b)$

while $\text{degree}(r) \geq d$ do
$e = \text{degree}(r) - d$
$s = \frac{\text{leadingCoefficient}(r)}{c} x^e$
$q = q + s$
$r = r - sb$
endwhile
return (q, r)
end

For example, given

$p_1 := (x+1) \ast (x+6)$
$p_2 := (x+1) \ast (x-6)$
gcd(p1,p2) -> x+1

In Gathen [?] we find a discussion of applying the Euclidean algorithm to elements of a field. In a field every nonzero rational number is a unit. If we want to define a single element such that
\[ \gcd(f, g) \in \mathbb{Q}[x] \]
we choose a monic polynomial, that is, the element with a leading coefficient of 1. So
\[ \text{abs}(a/ \text{leadingCoefficient}(a)) \]
defines a normal form of a.
Gathen also notes that for polynomials we should modify the Euclidean algorithm so all remainders are normalized. Without this constraint the remainders will have huge numerators
and denominators.

Hensel’s lifting lemma states that if a polynomial equation has a simple root modulo a prime number \( p \), then this root corresponds to a unique root of the same equation modulo any higher power of \( p \), which can be found by iteratively “lifting” the solution modulo successive powers of \( p \).

See Volume 10.1 for more details.

++ over the integers.

PolynomialNumberTheoryFunctions(): Exports == Implementation where
I ==> Integer
RN ==> Fraction I
SUP ==> SparseUnivariatePolynomial
NNI ==> NonNegativeInteger

Exports ==> with
 bernoulli : I -> SUP RN
   ++ bernoulli(n) returns the nth Bernoulli polynomial \spad{B[n](x)}.
   ++ Bernoulli polynomials denoted \spad{B(n,x)} computed by solving the
   ++ differential equation \spad{differentiate(B(n,x),x) = n B(n-1,x)} where
   ++ \spad{B(0,x) = 1} and initial condition comes from \spad{B(n) = B(n,0)}.
 chebyshevT: I -> SUP I
   ++ chebyshevT(n) returns the nth Chebyshev polynomial \spad{T[n](x)}.
   ++ Note that Chebyshev polynomials of the first kind,
   ++ denoted \spad{T[n](x)},
   ++ computed from the two term recurrence. The generating function
   ++ \spad{(1-t*x)/(1-2*t*x+t**2) = sum(T[n](x)*t**n, n=0..infinity)}.
 chebyshevU: I -> SUP I
   ++ chebyshevU(n) returns the nth Chebyshev polynomial \spad{U[n](x)}. 
++ Note that Chebyshev polynomials of the second kind,  
++ denoted \texttt{U[n](x)},  
++ computed from the two term recurrence. The generating function  
++ \texttt{1/(1-2*t*x+t**2) = sum(T[n](x)*t**n, n=0..infinity)}.  

cyclotomic: I -> SUP I  
++ cyclotomic(n) returns the nth cyclotomic polynomial \texttt{phi[n](x)}.  
++ Note that \texttt{phi[n](x)} is the factor of \texttt{x**n - 1} whose roots  
++ are the primitive nth roots of unity.  
euler : I -> SUP RN  
++ euler(n) returns the nth Euler polynomial \texttt{E[n](x)}.  
++ Note that Euler polynomials denoted \texttt{E(n,x)} computed by solving  
++ the differential equation  
++ \texttt{spaddifferentiate(E(n,x),x) = n E(n-1,x)} where  
++ \texttt{spad(E(0,x) = 1)} and initial condition comes  
++ from \texttt{spad(E(n) = 2**n E(n,1/2)}}.  

fixedDivisor: SUP I -> I  
++ fixedDivisor(a) for \texttt{a(x)} in \texttt{Z[x]} is the largest integer  
++ f such that f divides \texttt{a(x=k)} for all integers k.  
++ Note that fixed divisor of \texttt{a} is  
++ \texttt{reduce(gcd,[a(x=k) for k in 0..degree(a)])}}.  

hermite : I -> SUP I  
++ hermite(n) returns the nth Hermite polynomial \texttt{H[n](x)}.  
++ Note that Hermite polynomials, denoted \texttt{H[n](x)}, are computed from  
++ the two term recurrence. The generating function is:  
++ \texttt{exp(2*t*x-t**2) = sum(H[n](x)*t**n/n!, n=0..infinity)}}.  

laguerre : I -> SUP I  
++ laguerre(n) returns the nth Laguerre polynomial \texttt{L[n](x)}.  
++ Note that Laguerre polynomials, denoted \texttt{L[n](x)}, are computed  
++ from the two term recurrence. The generating function is:  
++ \texttt{exp(x*t/(t-1))/(1-t) = sum(L[n](x)*t**n/n!, n=0..infinity)}}.  

legendre : I -> SUP RN  
++ legendre(n) returns the nth Legendre polynomial \texttt{P[n](x)}.  
++ Note that Legendre polynomials, denoted \texttt{P[n](x)}, are computed  
++ from the two term recurrence. The generating function is:  
++ \texttt{spad(1/sqrt(1-2*t*x+t**2) = sum(P[n](x)*t**n, n=0..infinity)}}.

Exports == with
removeRedundantFactors: LP -> LP
++ \{axiom\{removeRedundantFactors(lp)\} returns \{axiom\{lq\} such that if
++ \{axiom\{lp = [p₁,...,pn]\} and \{axiom\{lq = [q₁,...,qm]\}\}
++ then the product \{axiom\{p₁*p₂*...*pn\} vanishes iff the product \{axiom\{q₁*q₂*...*qm\} vanishes,
++ and the product of degrees of the \{axiom\{qᵢ\} is not greater than
++ the one of the \{axiom\{pᵢ\}, and no polynomial in \{axiom\{lq\}\}
++ divides another polynomial in \{axiom\{lq\}. In particular,
++ polynomials lying in the base ring \{axiom\{R\} are removed.
++ Moreover, \{axiom\{lq\} is sorted w.r.t \{axiom\{infRittWu?\}.
++ Furthermore, if \R is gcd-domain, the polynomials in \{axiom\{lq\} are
++ pairwise without common non trivial factor.

removeRedundantFactors: (P,P) -> LP
++ \{axiom\{removeRedundantFactors(p,q)\} returns the same as
++ \{axiom\{removeRedundantFactors([p,q])\}

removeSquaresIfCan : LP -> LP
++ \{axiom\{removeSquaresIfCan(lp)\} returns
++ \{axiom\{removeDuplicates [squareFreePart(p)$P for p in lp\}
++ if \{axiom\{R\} is gcd-domain else returns \{axiom\{lp\}.

unprotectedRemoveRedundantFactors: (P,P) -> LP
++ \{axiom\{unprotectedRemoveRedundantFactors(p,q)\} returns the same as
++ \{axiom\{removeRedundantFactors(p,q)\} but does assume that neither
++ \{axiom\{p\} nor \{axiom\{q\} lie in the base ring \{axiom\{R\} and assumes that
++ \{axiom\{infRittWu?(p,q)\} holds. Moreover, if \{axiom\{R\} is gcd-domain,
++ then \{axiom\{lp\} and \{axiom\{lq\} are assumed to be square free.

removeRedundantFactors: (LP,P) -> LP
++ \{axiom\{removeRedundantFactors(lp,q)\} returns the same as
++ \{axiom\{removeRedundantFactors(cons(q,lp))\} assuming
++ that \{axiom\{removeRedundantFactors(lp)\} returns \{axiom\{lp\}
++ up to replacing some polynomial \{axiom\{pj\} in \{axiom\{lp\}
++ by some some polynomial \{axiom\{qj\} associated to \{axiom\{pj\}.

removeRedundantFactors : (LP,LP) -> LP
++ \{axiom\{removeRedundantFactors(lp,lq)\} returns the same as
++ \{axiom\{removeRedundantFactors(concat(lp,lq))\} assuming
++ that \{axiom\{removeRedundantFactors(lp)\} returns \{axiom\{lp\}
++ up to replacing some polynomial \{axiom\{pj\} in \{axiom\{lp\}
++ by some polynomial \{axiom\{qj\} associated to \{axiom\{pj\}.

removeRedundantFactors : (LP,LP,(LP -> LP)) -> LP
++ \{axiom\{removeRedundantFactors(lp,lq,remOp)\} returns the same as
++ \{axiom\{concat(remOp(removeRoughlyRedundantFactorsInPols(lp,lq)),lq)\}
++ assuming that \{axiom\{remOp(lq)\} returns \{axiom\{lq\} up to similarity.

certainlySubVariety? : (LP,LP) -> B
++ \{axiom\{certainlySubVariety?(newlp,lp)\} returns true iff for every \{axiom\{p\}
++ in \{axiom\{lp\} the remainder of \{axiom\{p\} by \{axiom\{newlp\} using the division algorithm
++ of Groebner techniques is zero.

possiblyNewVariety? : (LP, List LP) -> B
++ \{axiom\{possiblyNewVariety?(newlp,lp)\} returns true iff for every \{axiom\{lp\}
++ in \{axiom\{lp\} certainlySubVariety?(newlp,lp) does not hold.

probablyZeroDim?: LP -> B
++ \{axiom\{probablyZeroDim?(lp)\} returns true iff the number of polynomials
++ in \{axiom\{lp\} is not smaller than the number of variables occurring
++ in these polynomials.
selectPolynomials : ((P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \text{\texttt{selectPolynomials(pred?,ps)}} returns \texttt{gps,bps} where
++ such that \texttt{pred?(p)} holds and \texttt{bps} are the other ones.
selectOrPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \text{\texttt{selectOrPolynomials(lpred?,ps)}} returns \texttt{gps,bps} where
++ \texttt{gps} is a list of the polynomial \texttt{p} in \texttt{ps}
++ such that \texttt{pred?(p)} holds for some \texttt{pred?} in \texttt{lpred?}
++ and \texttt{bps} are the other ones.
selectAndPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \text{\texttt{selectAndPolynomials(lpred?,ps)}} returns \texttt{gps,bps} where
++ \texttt{gps} is a list of the polynomial \texttt{p} in \texttt{ps}
++ such that \texttt{pred?(p)} holds for every \texttt{pred?} in \texttt{lpred?}
++ and \texttt{bps} are the other ones.
quasiMonicPolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \text{\texttt{quasiMonicPolynomials(lp)}} returns \texttt{qmps,nqmps} where
++ \texttt{qmps} is a list of the quasi-monic polynomials in \texttt{lp}
++ and \texttt{nqmps} are the other ones.
univariate? : P -> B
++ \text{\texttt{univariate?}(p)} returns true iff \texttt{p} involves one and
++ only one variable.
univariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \text{\texttt{univariatePolynomials(lp)}} returns \texttt{ups,nups} where
++ \texttt{ups} is a list of the univariate polynomials,
++ and \texttt{nups} are the other ones.
linear? : P -> B
++ \text{\texttt{linear?}(p)} returns true iff \texttt{p} does not lie
++ in the base ring \texttt{R} and has main degree \texttt{1}.
linearPolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \text{\texttt{linearPolynomials(lp)}} returns \texttt{lps,nlps} where
++ \texttt{lps} is a list of the linear polynomials in \texttt{lp},
++ and \texttt{nlps} are the other ones.
bivariate? : P -> B
++ \text{\texttt{bivariate?}(p)} returns true iff \texttt{p} involves two and
++ only two variables.
bivariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \text{\texttt{bivariatePolynomials(lp)}} returns \texttt{bps,nbps} where
++ \texttt{bps} is a list of the bivariate polynomials,
++ and \texttt{nbps} are the other ones.
removeRoughlyRedundantFactorsInPols : (LP,LP) -> LP
++ \text{\texttt{removeRoughlyRedundantFactorsInPols(lp,lf)}} returns
++ \texttt{newlp} where \texttt{newlp} is obtained from \texttt{lp}
++ by removing in every polynomial \texttt{p} of \texttt{lp}
++ any occurrence of a polynomial \texttt{f} in \texttt{lf}.
++ This may involve a lot of exact-quotients computations.
removeRoughlyRedundantFactorsInPols : (LP,LP,B) -> LP
++ \text{\texttt{removeRoughlyRedundantFactorsInPols(lp,lf,opt)}} returns
++ the same as \texttt{removeRoughlyRedundantFactorsInPols(lp,lf)}
++ if \texttt{opt} is \texttt{false} and if the previous operation
CHAPTER 17. CHAPTER P

++ does not return any non null and constant polynomial,

This package computes square-free decomposition of multivariate polynomials over a coefficient ring which is an arbitrary gcd domain. The requirement on the coefficient domain guarantees that the content can be removed so that factors will be primitive as well as square-free. Over an infinite ring of finite characteristic, it may not be possible to guarantee that the factors are square-free.

    denomRicDE: L -> UP
    ++ denomRicDE(op) returns a polynomial \spad{d} such that any rational
    ++ solution of the associated Riccati equation of \spad{op y = 0} is
    ++ of the form \spad{p/d + q'/q + r} for some polynomials p and q
    ++ and a reduced r. Also, \spad{deg(p) < deg(d)} and \{gcd(d,q) = 1\}.
    leadingCoefficientRicDE: L -> List REC
    ++ leadingCoefficientRicDE(op) returns
    ++ \spad{[[m1, p1], [m2, p2], ... , [mk, pk]]} such that the polynomial
    ++ part of any rational solution of the associated Riccati equation of
    ++ \spad{op y = 0} must have degree mj for some j, and its leading
    ++ coefficient is then a zero of pj. In addition,\spad{m1>m2> ... >mk}.
    constantCoefficientRicDE: (L, UP -> List F) -> List CNT
    ++ constantCoefficientRicDE(op, ric) returns
    ++ \spad{[[a1, L1], [a2, L2], ... , [ak, Lk]]} such that any rational
    ++ solution with no polynomial part of the associated Riccati equation of
    ++ \spad{op y = 0} must be one of the ai's in which case the equation for
    ++ \spad{z = y e^{-\text{int} ai}} is \spad{L_i z = 0}.
    ++ \spad{ric} is a Riccati equation solver over \spad{F}, whose input
    ++ is the associated linear equation.
    polyRicDE: (L, UP -> List F) -> List POL
    ++ polyRicDE(op, zeros) returns
    ++ \spad{[[p1, L1], [p2, L2], ... , [pk, Lk]]} such that the polynomial
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the \( pi \)'s (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-\int p}} is \spad{Li z =0}.
++ \spad{zeros} is a zero finder in \spad{UP}.

\textbf{singRicDE:} \((L, (UP, UP2) \rightarrow \text{List} \ UP, \ UP \rightarrow \text{Factored} \ UP) \rightarrow \text{List} \ \text{FRC}
++ \text{singRicDE}(op, zeros, ezfactor) returns
++ \spad{[[f1, L1], [f2, L2], \ldots, [fk, Lk]]} such that the singular
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the \( fi \)'s (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-\int p}} is \spad{Li z=0}.
++ \spad{zeros\spad{C(x),H(x,y)}} returns all the \spad{P_i(x)}'s such that
++ \spad{H(x,P_i(x)) = 0 \text{ modulo } C(x)}.
++ Argument \spad{ezfactor} is a factorisation in \spad{UP},
++ not necessarily into irreducibles.

\textbf{changeVar:} \((L, UP) \rightarrow L

PseudoRemainderSequence examples
====================================================================

The package constructor PseudoRemainderSequence provides
efficient algorithms by Lionel Ducos (University of Poitiers, France)
for computing sub-resultants. This leads to a speed up in many places
in Axiom where sub-resultants are computed (polynomial system solving,
algebraic factorization, integration).

This package contains some functions from improvements of the
subresultants algorithm.

—— package PRS PseudoRemainderSequence ——

)abbrev package PRS PseudoRemainderSequence
++ Author: Ducos Lionel (Lionel.Ducos@mathlabo.univ-poitiers.fr)
++ Date Created: january 1995
++ Date Last Updated: 5 february 1999
++ References :
++ Lionel Ducos ‘‘Optimizations of the subresultant algorithm’’
++ Description:
++ This package contains some functions: discriminant, resultant,
++ subResultantGcd, chainSubResultants, degreeSubResultant, lastSubResultant,
++ resultantEuclidean, subResultantGcdEuclidean, semiSubResultantGcdEuclidean1,
++ semiSubResultantGcdEuclidean2
++ These procedures come from improvements of the subresultants algorithm.

PseudoRemainderSequence(R, polR) : Specification == Implementation where
R : IntegralDomain
polR : UnivariatePolynomialCategory(R)
NNI ==> NonNegativeInteger
LC ==> leadingCoefficient

Specification == with
resultant : (polR, polR) -> R
++ \texttt{resultant(P, Q)} returns the resultant
++ of \texttt{\texttt{axiom}(P)} and \texttt{\texttt{axiom}(Q)}

resultantEuclidean : (polR, polR) ->
  Record(coef1 : polR, coef2 : polR, resultant : R)
++ \texttt{\texttt{axiom}(resultantEuclidean(P, Q))} carries out the equality
++ \axiom{coef1*P + coef2*Q = resultant(P,Q)}

semiResultantEuclidean2 : (polR, polR) ->
  Record(coef2 : polR, resultant : R)
++ \axiom{semiResultantEuclidean2(P,Q)} carries out the equality
++ \axiom{...P + coef2*Q = resultant(P,Q)}.
++ Warning. \axiom{degree(P) >= degree(Q)}.

semiResultantEuclidean1 : (polR, polR) ->
  Record(coef1 : polR, resultant : R)
++ \axiom{semiResultantEuclidean1(P,Q)} carries out the equality
++ \axiom{coef1*P + ? Q = resultant(P,Q)}.

indiceSubResultant : (polR, polR, NNI) -> polR
++ \axiom{indiceSubResultant(P, Q, i)} returns
++ the subresultant of indice \axiom{i}

indiceSubResultantEuclidean : (polR, polR, NNI) ->
  Record(coef1 : polR, coef2 : polR, subResultant : polR)
++ \axiom{indiceSubResultantEuclidean(P, Q, i)} returns
++ the subresultant \axiom{S_i(P,Q)} and carries out the equality
++ \axiom{coef1*P + coef2*Q = S_i(P,Q)}

semiindiceSubResultantEuclidean : (polR, polR, NNI) ->
  Record(coef2 : polR, subResultant : polR)
++ \axiom{semiindiceSubResultantEuclidean(P, Q, i)} returns
++ the subresultant \axiom{S_i(P,Q)} and carries out the equality
++ \axiom{...P + coef2*Q = S_i(P,Q)}
++ Warning. \axiom{degree(P) >= degree(Q)}.

degreeSubResultant : (polR, polR, NNI) -> polR
++ \axiom{degreeSubResultant(P, Q, d)} computes
++ a subresultant of degree \axiom{d}.

degreeSubResultantEuclidean : (polR, polR, NNI) ->
  Record(coef1 : polR, coef2 : polR, subResultant : polR)
++ \axiom{degreeSubResultantEuclidean(P, Q, i)} returns
++ a subresultant \axiom{S} of degree \axiom{d}
++ and carries out the equality \axiom{coef1*P + coef2*Q = S_i}.

semiDegreeSubResultantEuclidean : (polR, polR, NNI) ->
  Record(coef2 : polR, subResultant : polR)
++ \axiom{semiDegreeSubResultantEuclidean(P, Q, i)} returns
++ a subresultant \axiom{S} of degree \axiom{d}
++ and carries out the equality \axiom{...P + coef2*Q = S_i}.
++ Warning. \axiom{degree(P) >= degree(Q)}.

lastSubResultant : (polR, polR) -> polR
++ \axiom{lastSubResultant(P, Q)} computes
++ the last non zero subresultant of \axiom{P} and \axiom{Q}
lastSubResultantEuclidean : (polR, polR) ->
  Record(coef1 : polR, coef2 : polR, subResultant : polR)
  ++ \texttt{lastSubResultantEuclidean}(P, Q) computes
  ++ the last non zero subresultant \texttt{subResultant}
  ++ and carries out the equality \texttt{coef1*P + coef2*Q = S}.

semiLastSubResultantEuclidean : (polR, polR) ->
  Record(coef2 : polR, subResultant : polR)
  ++ \texttt{semiLastSubResultantEuclidean}(P, Q) computes
  ++ the last non zero subresultant \texttt{subResultant}
  ++ and carries out the equality \texttt{...P + coef2*Q = S}.
  ++ Warning. \texttt{degree(P) >= degree(Q)}.

subResultantGcd : (polR, polR) -> polR
  ++ \texttt{subResultantGcd}(P, Q) returns the gcd
  ++ of two primitive polynomials \texttt{P} and \texttt{Q}.

subResultantGcdEuclidean : (polR, polR) -> Record(coef1 : polR, coef2 : polR, gcd : polR)
  ++ \texttt{subResultantGcdEuclidean}(P, Q) carries out the equality
  ++ \texttt{coef1*P + coef2*Q = +/- S_i(P,Q)}
  ++ where the degree (not the indice)
  ++ of the subresultant \texttt{S_i(P,Q)} is the smaller as possible.

semiSubResultantGcdEuclidean1 : (polR, polR) -> Record(coef1 : polR, gcd : polR)
  ++ \texttt{semiSubResultantGcdEuclidean1}(P, Q) carries out the equality
  ++ \texttt{coef1*P + ? Q = +/- S_i(P,Q)}
  ++ where the degree (not the indice)
  ++ of the subresultant \texttt{S_i(P,Q)} is the smaller as possible.

semiSubResultantGcdEuclidean2 : (polR, polR) -> Record(coef2 : polR, gcd : polR)
  ++ \texttt{semiSubResultantGcdEuclidean2}(P, Q) carries out the equality
  ++ \texttt{...P + coef2*Q = +/- S_i(P,Q)}
  ++ where the degree (not the indice)
  ++ of the subresultant \texttt{S_i(P,Q)} is the smaller as possible.
  ++ Warning. \texttt{degree(P) >= degree(Q)}.

semiDiscriminantEuclidean : polR -> Record(coef2 : polR, discriminant : R)
  ++ \texttt{semiDiscriminantEuclidean}(P) carries out the equality
  ++ \texttt{coef1 * P + coef2 * D(P) = discriminant(P)}.

semiDiscriminantEuclidean : polR ->
  Record(coef2 : polR, discriminant : R)
++ \texttt{discriminantEuclidean(P)} carries out the equality
++ \texttt{...P + coef2 * D(P) = discriminant(P)}.
++ Warning. \texttt{degree(P) >= degree(Q)}.

\texttt{chainSubResultants : (polR, polR) -> List(polR)}
++ \texttt{chainSubResultants(P, Q)} computes the list
++ of non zero subresultants of \texttt{axiom(P)} and \texttt{axiom(Q)}.

\texttt{schema : (polR, polR) -> List(NNI)}
++ \texttt{schema(P,Q)} returns the list of degrees of
++ non zero subresultants of \texttt{axiom(P)} and \texttt{axiom(Q)}.

if R has GcdDomain then
resultantReduit : (polR, polR) -> R
++ \texttt{resultantReduit(P,Q)} returns the "reduce resultant"
++ of \texttt{axiom(P)} and \texttt{axiom(Q)}.

resultantReduitEuclidean : (polR, polR) ->
\texttt{Record(coef1 : polR, coef2 : polR, resultantReduit : R)}
++ \texttt{resultantReduitEuclidean(P,Q)} returns
++ the "reduce resultant" and carries out the equality
++ \texttt{\ldots P + coef2*Q = resultantReduit(P,Q)}.

semiResultantReduitEuclidean : (polR, polR) ->
\texttt{Record(coef2 : polR, resultantReduit : R)}
++ \texttt{semiResultantReduitEuclidean(P,Q)} returns
++ the "reduce resultant" and carries out the equality
++ \texttt{\ldots P + coef2*Q = resultantReduit(P,Q)}.

gcd : (polR, polR) -> polR
++ \texttt{gcd(P, Q)} returns the gcd of \texttt{axiom(P)} and \texttt{axiom(Q)}.

-- sub-routines exported for convenience -----------------------------

"*" : (R, Vector(polR)) -> Vector(polR)
++ \texttt{r * v} computes the product of \texttt{axiom(r)} and \texttt{axiom(v)}

"exquo" : (Vector(polR), R) -> Vector(polR)
++ \texttt{v exquo r} computes
++ the exact quotient of \texttt{axiom(v)} by \texttt{axiom(r)}

pseudoDivide : (polR, polR) ->
\texttt{Record(coef:R, quotient:polR, remainder:polR)}
++ \texttt{pseudoDivide(P,Q)} computes the pseudoDivide
++ of \texttt{axiom(P)} by \texttt{axiom(Q)}.

divide : (polR, polR) -> Record(quotient : polR, remainder : polR)
++ \texttt{divide(F,G)} computes quotient and rest
++ of the exact euclidean division of \texttt{axiom(F)} by \texttt{axiom(G)}.
Lazard : (R, R, NNI) -> R  
++ \axiom{Lazard(x, y, n)} computes \axiom{x**n/y**(n-1)}

Lazard2 : (polR, R, R, NNI) -> polR  
++ \axiom{Lazard2(F, x, y, n)} computes \axiom{(x/y)**(n-1) * F}

next_sousResultant2 : (polR, polR, polR, R) -> polR  
++ \axiom{nextsousResultant2(P, Q, Z, s)} returns  
++ the subresultant \axiom{S_{e-1}} where  
++ \axiom{P ~ S_d, Q = S_{d-1}, Z = S_e, s = lc(S_d)}

resultant_naif : (polR, polR) -> R  
++ \axiom{resultantEuclidean_naif(P, Q)} returns  
++ the resultant of \axiom{P} and \axiom{Q} computed  
++ by means of the naive algorithm.

resultantEuclidean_naif : (polR, polR) -> Record(coef1 : polR, coef2 : polR, resultant : R)  
++ \axiom{resultantEuclidean_naif(P, Q)} returns  
++ the extended resultant of \axiom{P} and \axiom{Q} computed  
++ by means of the naive algorithm.

semiResultantEuclidean_naif : (polR, polR) -> Record(coef2 : polR, resultant : R)  
++ \axiom{resultantEuclidean_naif(P, Q)} returns  
++ the semi-extended resultant of \axiom{P} and \axiom{Q} computed  
++ by means of the naive algorithm.

FAIL==> error "failed - cannot handle that integrand"

Exports ==> with
  palgint : (F, K, K) -> IR
    ++ palgint(f, x, y) returns the integral of \spad{f(x,y)dx}
    ++ where y is an algebraic function of x.
  palgextint: (F, K, K, F) -> U2
    ++ palgextint(f, x, y, g) returns functions \spad{[h, c]}
    ++ such that \spad{dh/dx = f(x,y) - c g}, where y is an algebraic function of x;
    ++ returns "failed" if no such functions exist.
  palglimint: (F, K, K, List F) -> U3
    ++ palglimint(f, x, y, [u1,...,un]) returns functions
    ++ such that \spad{d(h + sum(ci log(ui)))/dx = f(x,y)} if such functions exist,
    ++ "failed" otherwise;
    ++ y is an algebraic function of x.
  palgRDE : (F, F, F, K, K, (F, F, SY) -> U1) -> U1
    ++ palgRDE(nfp, f, g, x, y, foo) returns a function \spad{z(x,y)}
    ++ such that \spad{dz/dx + n * df/dx z(x,y) = g(x,y)} if such a z exists,
    ++ "failed" otherwise;
    ++ y is an algebraic function of x;
    ++ \spad{foo(a, b, x)} is a function that solves
    ++ \spad{du/dx + n * da/dx u(x) = u(x)}
    ++ for an unknown \spad{u(x)} not involving y.
    ++ \spad{nfp} is \spad{n * df/dx}.
if L has LinearOrdinaryDifferentialOperatorCategory F then
  palgLODE: (L, F, K, K, SY) -> REC
    ++ palgLODE(op, g, kx, y, x) returns the solution of \spad{op f = g}.
    ++ y is an algebraic function of x.

=================================================================================
QuasiAlgebraicSet2 examples
=================================================================================

QuasiAlgebraicSet2 adds a function radicalSimplify which uses
IdealDecompositionPackage to simplify the representation of a
quasi-algebraic set.
A quasi-algebraic set is the intersection of a Zariski closed set, defined as the common zeros of a given list of polynomials (the defining polynomials for equations), and a principal Zariski open set, defined as the complement of the common zeros of a polynomial $f$ (the defining polynomial for the inequation).

Quasi-algebraic sets are implemented in the domain QuasiAlgebraicSet, where two simplification routines are provided: idealSimplify and simplify.

The function radicalSimplify is added for comparison study only.

Because the domain IdealDecompositionPackage provides facilities for computing with radical ideals, it is necessary to restrict the ground ring to the domain Fraction Integer, and the polynomial ring to be of type DistributedMultivariatePolynomial.

The routine radicalSimplify uses these to compute groebner basis of radical ideals and is inefficient and restricted when compared to the two in QuasiAlgebraicSet.

**QuasiAlgebraicSet2 (QALGSET2)**

Exports:
radicalSimplify

---

package QALGSET2 QuasiAlgebraicSet2
\textbf{Description:}

\texttt{\spadtype{QuasiAlgebraicSet2}} adds a function \texttt{\spadfun{radicalSimplify}}
which uses \texttt{\spadtype{IdealDecompositionPackage}} to simplify
the representation of a quasi-algebraic set. A quasi-algebraic set
is the intersection of a Zariski closed set, defined as the common zeros of a given list of
polynomials (the defining polynomials for equations), and a principal Zariski open set, defined as the complement of the common zeros of a polynomial \(f\) (the defining polynomial for the inequation).

Quasi-algebraic sets are implemented in the domain \texttt{\spadtype{QuasiAlgebraicSet}}, where two simplification routines are provided:
\texttt{\spadfun{idealSimplify}} and \texttt{\spadfun{simplify}}.

The function \texttt{\spadfun{radicalSimplify}} is added for comparison study only. Because the domain \texttt{\spadtype{IdealDecompositionPackage}} provides facilities for computing with radical ideals, it is necessary to restrict
the ground ring to the domain \texttt{\spadtype{Fraction Integer}}, and the polynomial ring to be of type \texttt{\spadtype{DistributedMultivariatePolynomial}}.

The routine \texttt{\spadfun{radicalSimplify}} uses these to compute groebner basis of radical ideals and
is inefficient and restricted when compared to the two in \texttt{\spadtype{QuasiAlgebraicSet}}.

====================================================================
QuaternionCategoryFunctions2 examples
====================================================================

QuaternionCategoryFunctions2 implements functions between two
quaternion domains. The function map is used by the system
interpreter to coerce between quaternion types.

The package QuaternionCategoryFunctions2 provides a function map
to convert an expression in Quaternion(R) to an expression in
Quaternion(S) using the function f.

q := quatern(2/11,-8,3/4,1)

 2 3
-- - 8i + - j + k
11 4

Type: Quaternion Fraction Integer
\[
\begin{align*}
2 & \quad 3 \\
11 & \quad 4
\end{align*}
\]

Type: Quaternion Complex Fraction Integer

```plaintext
)abbrev package REP RadicalEigenPackage
++ Author: P.Gianni
++ Date Created: Summer 1987
++ Date Last Updated: October 1992
++ Description:
++ This package works for matrices with coefficients which are
++ rational functions over the integers.
++ (see \spadtype{Fraction Polynomial Integer}).
++ The eigenvalues and eigenvectors are expressed in terms of radicals.

RadicalEigenPackage() : C == T
where
R ==> Integer
P ==> Polynomial R
F ==> Fraction P
RE ==> Expression R
SE ==> Symbol()
```
M ==> Matrix(F)
MRE ==> Matrix(RE)
ST ==> SuchThat(SE,P)
NNI ==> NonNegativeInteger

EigenForm ==> Record(eigval:Union(F,ST),eigmult:NNI,eigvec:List(M))
RadicalForm ==> Record(radval:RE,radmult:Integer,radvect:List(MRE))

C == with
  radicalEigenvectors : M -> List(RadicalForm)
  ++ radicalEigenvectors(m) computes
  ++ the eigenvalues and the corresponding eigenvectors of the
  ++ matrix m;
  ++ when possible, values are expressed in terms of radicals.

  radicalEigenvector : (RE,M) -> List(MRE)
  ++ radicalEigenvector(c,m) computes the eigenvector(s) of the
  ++ matrix m corresponding to the eigenvalue c;
  ++ when possible, values are
  ++ expressed in terms of radicals.

  radicalEigenvalues : M -> List RE
  ++ radicalEigenvalues(m) computes the eigenvalues of the matrix m;
  ++ when possible, the eigenvalues are expressed in terms of radicals.

  eigenMatrix : M -> Union(MRE,"failed")
  ++ eigenMatrix(m) returns the matrix b
  ++ such that \spad{b*m*(inverse b)} is diagonal,
  ++ or "failed" if no such b exists.

  normalise : MRE -> MRE
  ++ normalise(v) returns the column
  ++ vector v
  ++ divided by its euclidean norm;
  ++ when possible, the vector v is expressed in terms of radicals.

  gramschmidt : List(MRE) -> List(MRE)
  ++ gramschmidt(lv) converts the list of column vectors lv into
  ++ a set of orthogonal column vectors
  ++ of euclidean length 1 using the Gram-Schmidt algorithm.

  orthonormalBasis : M -> List(MRE)
  ++ orthonormalBasis(m) returns the orthogonal matrix b such that
  ++ \spad{b*m*(inverse b)} is diagonal.
  ++ Error: if m is not a symmetric matrix.

package RATFACT RationalFactorize

package RATFACT RationalFactorize
Factorization of extended polynomials with rational coefficients. This package implements factorization of extended polynomials whose coefficients are rational numbers. It does this by taking the lcm of the coefficients of the polynomial and creating a polynomial with integer coefficients. The algorithm in GaloisGroupFactorizer is then used to factor the integer polynomial. The result is normalized with respect to the original lcm of the denominators.

RationalFunctionSum examples

Computes sums of rational functions.

There are 4 different forms of the sum operator in this domain. They are variations of the types of the input

\[ \sum_{i=1}^{n} \frac{6i - 6i + 1}{12} \]

\[ \sum_{i=1}^{n} \frac{2}{i} \]

\[ \sum_{i=1}^{n} \frac{n + n}{2} \]
We can compute the sum form on part at a time to see what happens. First, we make a SegmentBinding(Polynomial(Integer)):

\[ s := i = 1 \ldots n \]

We pick out the upper and lower bounds of the segment:

\[ \text{hiseg} := \text{high}(\text{segment}(s)) \]
\[ n \]

\[ \text{loseg} := \text{low}(\text{segment}(s)) \]
\[ 1 \]

We pick out the variable from the segment:

\[ v := \text{variable } s \]
\[ i \]

We create a polynomial we wish to sum:

\[ p := i :: \text{Polynomial}(\text{Integer}) \]
\[ i \]

And we create the sum for that polynomial:

\[ f := \text{sum}(p, v) \]
\[ 2 \]
\[ 6i - 6i + 1 \]
The new evaluate it at the upper endpoint:

\[ t_1 := \text{eval}(f, v, (1 + \text{hiseg})) \]

\[ \frac{2}{12} \frac{6n + 6n + 1}{12} \]

And the lower endpoint:

\[ t_2 := \text{eval}(f, v, \text{loseg}) \]

\[ \frac{1}{12} \]

And we take the difference of the endpoints:

\[ t_1 - t_2 \]

\[ \frac{2}{2} \frac{n + n}{2} \]

package RINTERP RationalInterpolation

Introduction

This file contains a crude naïve implementation of rational interpolation, where the coefficients of the rational function are in any given field.

Questions and Outlook

- Maybe this file should be joined with pinterp.spad, where polynomial Lagrange interpolation is implemented. I have a second version that parallels the structure of pinterp.spad closely.
- There are probably better ways to implement rational interpolation. Maybe http://www.cs.ucsb.edu/~omer/personal/abstracts/rational.html contains something useful, but I don’t know.
- Comments welcome!

RationalInterpolation (RINTERP)

Exports:
interpolate

— package RINTERP RationalInterpolation —

)abbrev package RINTERP RationalInterpolation
++ Description:
++ This package exports rational interpolation algorithms
RationalInterpolation(xx,F): Exports == Implementation where
  xx: Symbol
  F: Field
Exports == with
interpolate: (List F, List F, NonNegativeInteger,
             NonNegativeInteger) -> Fraction Polynomial F

— package RINTERP RationalInterpolation —

The implementation sets up a system of linear equations and solves it.
— package RINTERP RationalInterpolation —

Implementation == add
interpolate(xlist, ylist, m, k) ==

First we check whether we have the right number of points and values. Clearly the number of points and the number of values must be identical. Note that we want to determine the numerator and denominator polynomials only up to a factor. Thus, we want to determine
\(m + k + 1\) coefficients, where \(m\) is the degree of the polynomial in the numerator and \(k\) is the degree of the polynomial in the denominator.

In fact, we could also leave \(k\) unspecified and determine it as \(k=\#xlist-m-1\):

I don’t know whether this would be better.

The next step is to set up the matrix. Suppose that our numerator polynomial is \(p(x) = a_0 + a_1 x + \ldots + a_m x^m\) and that our denominator polynomial is \(q(x) = b_0 + b_1 x + \ldots + b_m x^m\). Then we have the following equations, writing \(n\) for \(m + k + 1\):

\[
\begin{align*}
p(x_1) - y_1 q(x_1) &= a_0 + a_1 x_1 + \ldots + a_m x_1^m - y_1 (b_0 + b_1 x_1 + \ldots + b_k x_1^k) = 0 \\
p(x_2) - y_2 q(x_2) &= a_0 + a_1 x_2 + \ldots + a_m x_2^m - y_2 (b_0 + b_1 x_2 + \ldots + b_k x_2^k) = 0 \\
&\vdots \\
p(x_n) - y_n q(x_n) &= a_0 + a_1 x_n + \ldots + a_m x_n^m - y_n (b_0 + b_1 x_n + \ldots + b_k x_n^k) = 0
\end{align*}
\]

This can be written as

\[
\begin{bmatrix}
1 & x_1 & \ldots & x_1^m & -y_1 & -y_1 x_1 & \ldots & -y_1 x_1^k \\
1 & x_2 & \ldots & x_2^m & -y_2 & -y_2 x_2 & \ldots & -y_2 x_2^k \\
& \vdots \\
1 & x_n & \ldots & x_n^m & -y_n & -y_n x_n & \ldots & -y_n x_2^k
\end{bmatrix}
\begin{bmatrix}
a_0 \\
a_1 \\
\vdots \\
a_m \\
b_0 \\
b_1 \\
\vdots \\
b_k
\end{bmatrix} = 0
\]

We generate this matrix columnwise:

```plaintext
package RINTERP RationalInterpolation

tempvec: List F := [1 for i in 1..(m+k+1)]
collist: List List F := cons(tempvec,
    [(tempvec := [tempvec.i * xlist.i -
        for i in 1..(m+k+1)]) _
     for j in 1..max(m,k)])
collist := append([collist.j for j in 1..(m+1)], _
    [- collist.j.i * ylist.i for i in 1..(m+k+1)] _
    for j in 1..(k+1)])
```
Now we can solve the system:

```plaintext
res: List Vector F := nullSpace((transpose matrix collist) ::Matrix F)
```

Note that it may happen that the system has several solutions. In this case, some of the data points may not be interpolated correctly. However, the solution is often still useful, thus we do not signal an error.

```plaintext
if #res~1 then output("Warning: unattainable points!" ::OutputForm)$OutputPackage
```

In this situation, all the solutions will be equivalent, thus we can always simply take the first one:

```plaintext
reslist: List List Polynomial F :=
    [[(res.1).(i+1)*(xx::Polynomial F)**i for i in 0..m],
    [(res.1).(i+m+2)*(xx::Polynomial F)**i for i in 0..k]]
```

Finally, we generate the rational function:

```plaintext
reduce(_,reslist.1)/reduce(_,reslist.2)
```

)abbrev package ODERAT RationalLODE
++ Author: Manuel Bronstein
++ Date Created: 13 March 1991
++ Date Last Updated: 13 April 1994
++ Description:
++ \spad{RationalLODE} provides functions for in-field solutions of linear
++ ordinary differential equations, in the rational case.

RationalLODE(F, UP): Exports == Implementation where
  F : Join(Field, CharacteristicZero, RetractableTo Integer,
          RetractableTo Fraction Integer)
  UP : UnivariatePolynomialCategory F

N ==> NonNegativeInteger
Z ==> Integer
RF ==> Fraction UP
U ==> Union(RF, "failed")
V ==> Vector F
M ==> Matrix F
LODO ==> LinearOrdinaryDifferentialOperator1 RF
LODO2==> LinearOrdinaryDifferentialOperator2(UP, RF)

Exports == with
  ratDsolve: (LODO, RF) -> Record(particular: U, basis: List RF)
    ++ ratDsolve(op, g) returns \spad{["failed", []]} if the equation
    ++ \spad{op y = g} has no rational solution. Otherwise, it returns
    ++ \spad{[f, [y1,\ldots,ym]]} where f is a particular rational solution
    ++ and the yi’s form a basis for the rational solutions of the
    ++ homogeneous equation.
  ratDsolve: (LODO, List RF) -> Record(basis:List RF, mat:Matrix F)
++ ratDsolve(op, [g1,...,gm]) returns \spad{[[h1,...,hq], M]} such ++ that any rational solution of \spad{op y = c1 g1 + ... + cm gm} ++ is of the form \spad{d1 h1 + ... + dq hv} where ++ \spad{M [d1,...,dq, c1,...,cm] = 0}.

ratDsolve: (LODO2, RF) -> Record(particular: U, basis: List RF) ++ ratDsolve(op, g) returns \spad{["failed", []]} if the equation ++ \spad{op y = g} has no rational solution. Otherwise, it returns ++ \spad{[f, [y1,...,ym]]} where f is a particular rational solution ++ and the yi's form a basis for the rational solutions of the ++ homogeneous equation.

ratDsolve: (LODO2, List RF) -> Record(basis:List RF, mat:Matrix F) ++ ratDsolve(op, [g1,...,gm]) returns \spad{[[h1,...,hq], M]} such ++ that any rational solution of \spad{op y = c1 g1 + ... + cm gm} ++ is of the form \spad{d1 h1 + ... + dq hv} where ++ \spad{M [d1,...,dq, c1,...,cm] = 0}.

indicialEquationAtInfinity: LODO -> UP ++ indicialEquationAtInfinity op returns the indicial equation of ++ \spad{op} at infinity.

indicialEquationAtInfinity: LODO2 -> UP ++ indicialEquationAtInfinity op returns the indicial equation of ++ \spad{op} at infinity.

—— package RURPK RationalUnivariateRepresentationPackage ——

)abbrev package RURPK RationalUnivariateRepresentationPackage
++ Author: Marc Moreno Maza
++ Date Created: 01/1999
++ Date Last Updated: 23/01/1999
++ Description:
++ A package for computing the rational univariate representation
++ of a zero-dimensional algebraic variety given by a regular
++ triangular set. This package is essentially an interface for the
++ \spadtype{InternalRationalUnivariateRepresentationPackage} constructor.
++ It is used in the \spadtype{ZeroDimensionalSolvePackage}
++ for solving polynomial systems with finitely many solutions.

RationalUnivariateRepresentationPackage(R,ls): Exports == Implementation where
R : Join(EuclideanDomain,CharacteristicZero)
ls: List Symbol
N ==> NonNegativeInteger
Z ==> Integer
P ==> Polynomial R
LP ==> List P
U ==> SparseUnivariatePolynomial(R)
RUR ==> Record(complexRoots: U, coordinates: LP)

Exports == with

  rur: (LP,Boolean) -> List RUR
  ++ \spad{rur(lp,univ?)} returns a rational univariate representation
  ++ of \spad{lp}. This assumes that \spad{lp} defines a regular
  ++ triangular \spad{ts} whose associated variety is zero-dimensional
  ++ over \spad{R}. \spad{rur(lp,univ?)} returns a list of items
  ++ \spad{\{u,lc\}} where \spad{u} is an irreducible univariate polynomial
  ++ and each \spad{c} in \spad{lc} involves two variables: one from \spad{ls},
  ++ called the coordinate of \spad{c}, and an extra variable which
  ++ represents any root of \spad{u}. Every root of \spad{u} leads to
  ++ a tuple of values for the coordinates of \spad{lc}. Moreover,
  ++ a point \spad{x} belongs to the variety associated with \spad{lp} iff
  ++ there exists an item \spad{\{u,lc\}} in \spad{rur(lp,univ?)} and
  ++ a root \spad{r} of \spad{u} such that \spad{x} is given by the
  ++ tuple of values for the coordinates of \spad{lc} evaluated at \spad{r}.
  ++ If \spad{univ?} is \spad{true} then each polynomial \spad{c}
  ++ will have a constant leading coefficient w.r.t. its coordinate.
  ++ See the example which illustrates the \spadtype{ZeroDimensionalSolvePackage}
  ++ package constructor.
  ++
  ++
  rur: (LP) -> List RUR
  ++ \spad{rur(lp)} returns the same as \spad{rur(lp,true)}
  ++
  rur: (LP,Boolean,Boolean) -> List RUR
  ++ \spad{rur(lp,univ?,check?)} returns the same as \spad{rur(lp,true)}.
  ++ Moreover, if \spad{check?} is \spad{true} then the result is checked.

package POLUTIL RealPolynomialUtilitiesPackage

This file describes the Real Closure 1.0 package which consists of different packages, categories and domains.

The package RealPolynomialUtilitiesPackage which receives a field and a univariate polynomial domain with coefficients in the field. It computes some simple functions such as Strum and Sylvester sequences.

The category RealRootCharacterizationCategory provides abstract functionalities to work with "real roots" of univariate polynomials. These resemble variables with some functionalities needed to compute important operations.

RealClosedField is a category with provides common operations available over real closed fields. These include finding all the roots of univariate polynomial, taking square roots, ...

CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like sqrt(2) + sqrt(2) you have two new variables which happen to be equal. To avoid this name the expression such as in s2 := sqrt(2) + s2

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

LIMITATIONS
The file reclos.input show some basic use of the package. This package uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several “real roots”.

Exports == with

\m tex{evalRec: (BasicOperator, Symbol, F, F, F, List F) \rightarrow F}
++ \spad{evalRec(u, dummy, n, n0, eq, values)} creates an expression that
++ stands for \(u(n0)\), where \(u(n)\) is given by the equation \(eq\). However, for
++ technical reasons the variable \(n\) has to be replaced by a dummy
++ variable \(dummy\) in \(eq\). The argument \(values\) specifies the initial values
++ of the recurrence \(u(0), u(1),\ldots\)
++ For the moment we don’t allow recursions that contain \(u\) inside of
++ another operator.

\m tex{evalADE: (BasicOperator, Symbol, F, F, F, List F) \rightarrow F}
++ \spad{evalADE(f, dummy, x, n, eq, values)} creates an expression that
++ stands for the coefficient of \(x^n\) in the Taylor expansion of \(f(x)\),
++ where \(f(x)\) is given by the functional equation \(eq\). However, for
++ technical reasons the variable \(x\) has to be replaced by a dummy
++ variable \(dummy\) in \(eq\). The argument \(values\) specifies the first few
++ Taylor coefficients.

getEq: F \rightarrow F
++ \spad{getEq f} returns the defining equation, if \(f\) represents the
++ coefficient of an ADE or a recurrence.

getOp: F \rightarrow BasicOperator
++ \spad{getOp f}, if \(f\) represents the coefficient of a recurrence or
++ ADE, returns the operator representing the solution

-- should be local

ord: Union(Integer, "failed"),
ker: Kernel F)
Implementation == add
\getchunk{implementation: RecurrenceOperator}

---

**Defining new operators**

We define two new operators, one for recurrences, the other for functional equations. The operators for recurrences represents the $n^{th}$ term of the corresponding sequence, the other the coefficient of $x^n$ in the Taylor series expansion.

---

**implementation: RecurrenceOperator**

```plaintext
oprecur := operator("rootOfRec":::Symbol)$BasicOperator
opADE := operator("rootOfADE":::Symbol)$BasicOperator

setProperty(oprecur, "%dummyVar", 2 pretend None)
setProperty(opADE, "%dummyVar", 2 pretend None)
```

Setting these properties implies that the second and third arguments of oprecur are dummy variables and affects tower$ES$: the second argument will not appear in tower$ES$, if it does not appear in any argument but the first and second. The third argument will not appear in tower$ES$, if it does not appear in any other argument. (%defsum is a good example)

The arguments of the two operators are as follows:

1. eq, i.e. the vanishing expression

---

**implementation: RecurrenceOperator**

```plaintext
eqAsF: List F -> F
eqAsF 1 == 1.1
```

---

2. dummy, a dummy variable to make substitutions possible

---

**implementation: RecurrenceOperator**

```plaintext
dummy: List F -> Symbol
dummy 1 == retract(1.2)$Symbol

dummyAsF: List F -> F
dummyAsF 1 == 1.2
```
3. The variable for display

   — implementation: RecurrenceOperator —

   displayVariable: List F -> F
   displayVariable l == l.3

4. operatorName(argument)

   — implementation: RecurrenceOperator —

   operatorName: List F -> BasicOperator
   operatorName l == operator(kernels(l.4).1)

   operatorNameAsF: List F -> F
   operatorNameAsF l == l.4

   operatorArgument: List F -> F
   operatorArgument l == argument(kernels(l.4).1).1

Concerning rootOfADE, note that although we have arg as argument of the operator, it is intended to indicate the coefficient, not the argument of the power series.

5. Values in reversed order.

   - rootOfRec: maybe values should be preceded by the index of the first given value. Currently, the last value is interpreted as \( f(0) \).
   - rootOfADE: values are the first few coefficients of the power series expansion in order.

   — implementation: RecurrenceOperator —

   initialValues: List F -> List F
   initialValues l == rest(l, 4)
Recurrences

Extracting some information from the recurrence

We need to find out whether we can determine the next term of the sequence, and how many initial values are necessary.

```

Setting the evaluation property of oprecur

irecur is just a wrapper that allows us to write a recurrence relation as an operator.

— implementation: RecurrenceOperator —

irecur: List F -> F
irecur l ==
evalRec(operatorName l, 
dummy l, displayVariable l, 
operatorArgument l, eqAsF l, initialValues l)
evaluate(oprecur, irecur)$BasicOperatorFunctions1(F)

Displaying a recurrence relation

— implementation: RecurrenceOperator —

ddrec: List F -> OutputForm
ddrec l ==
op := operatorName l
values := reverse l
eq := eqAsF l

numberOfValues := numberOfValuesNeeded(#values-4, op, dummy l, eq)
vals: List OutputForm
:= cons(eval(eq, dummyAsF l, displayVariable l)::OutputForm = _
0::OutputForm, 
[elt(op::OutputForm, [(i-1)::OutputForm]) = _
(values.i)::OutputForm
for i in 1..numberOfValues])
bracket(hconcat([(operatorNameAsF l)::OutputForm,
"": ",
comma Separate vals]))

setProperty(oprecur, "%specialDisp",
ddrec@(List F -> OutputForm) pretend None)
Functional Equations

Determining the number of initial values for ADE's

We use Joris van der Hoeven's instructions for ADE's. Given \( Q = p(f, f', \ldots, f^{(r)}) \) we first need to differentiate \( Q \) with respect to \( f^{(i)} \) for \( i \in \{0, 1, \ldots, r\} \), plug in the given truncated power series solution and determine the valuation.

— NOTYET implementation: RecurrenceOperator —

```lisp
getValuation(op, argsym, eq, maxorder, values): Integer ==
    max: Integer := -1;
    ker: Kernel F
    for i in 0..maxorder repeat
        ker := D(op(argsym), argsym, i)::Kernel F
        pol := univariate(eq, ker)
        dif := D pol
        ground numer(dif.D(op(argsym), argsym, i))
```

Extracting some information from the functional equation

getOrder returns the maximum derivative of \( op \) occurring in \( f \).

— implementation: RecurrenceOperator —

```lisp
getOrder(op: BasicOperator, f: Kernel F): NonNegativeInteger ==
    res: NonNegativeInteger := 0
    g := f
    while is?(g, %diff) repeat
        g := kernels(argument(g).1).1
        res := res+1
    if is?(g, op) then res else 0
```

Extracting a coefficient given a functional equation

— implementation: RecurrenceOperator —

```lisp
evalADE(op, argsym, argdisp, arg, eq, values) ==
    if not freeOf?(eq, retract(argdisp)@Symbol)
```
then error "RECOP: The argument should not be used in the equation of the ADE"

A package providing a new algorithm for solving polynomial systems by means of regular chains. Two ways of solving are proposed: in the sense of Zariski closure (like in Kalkbrener's algorithm) or in the sense of the regular zeros (like in Wu, Wang or Lazard methods). This algorithm is valid for any type of regular set. It does not care about the way a polynomial is added in a regular set, or how two quasi-components are compared (by an inclusion-test), or how the invertibility test is made in the tower of simple extensions associated with a regular set.

These operations are realized respectively by the domain TS and the packages QCMPACK(R,E,V,P,TS) and RSETGCD(R,E,V,P,TS).

The same way it does not care about the way univariate polynomial gcd (with coefficients in the tower of simple extensions associated with a regular set) are computed. The only requirement is that these gcd need to have invertible initials (normalized or not).

WARNING. There is no need for a user to call directly any operation of this package since they can be accessed by the domain TS. Thus, the operations of this package are not documented.

RepeatedSquaring examples

This code computes $x^n$ by repeated squaring. It takes advantage of the law of exponents so that if $n=a\cdot b$ then

$$x^n = x^a \cdot x^b$$

It also takes advantage of the fact that $n$ has a binary representation so that a one-bit right-shift of a number divides it by 2. Thus we get three cases:

- $n = 1 \rightarrow x^1$
- $n$ odd $\rightarrow$ repeatedsquare($x \cdot x$, $n/2$)$ \cdot x$
- $n$ even $\rightarrow$ repeatedsquare($x \cdot x$, $n/2$)

Since each recursive call divides $n$ by 2 the algorithm is $O(\log(n))$.

RepresentationPackage1 examples
====================================================================

RepresentationPackage1 provides functions for representation theory
for finite groups and algebras.

The package creates permutation representations and uses tensor products
and its symmetric and antisymmetric components to create new
representations of larger degree from given ones.

Note that instead of having parameters from Permutation this package
allows list notation of permutations as well: e.g. \([1,4,3,2]\) denotes
permutes 2 and 4 and fixes 1 and 3.

++ The package creates permutation representations and uses tensor products
and its symmetric and antisymmetric components to create new representations of larger degree from given ones. Note that instead of having parameters from \spadtype{Permutation} this package allows list notation of permutations as well: e.g. \spad{[1,4,3,2]} denotes permutes 2 and 4 and fixes 1 and 3.

RepresentationPackage2 examples

RepresentationPackage2 provides functions for working with modular representations of finite groups and algebra. The routines in this package are created, using ideas of R. Parker, (the meat-Axe) to get smaller representations from bigger ones, i.e. finding sub- and factormodules, or to show, that such the
representations are irreducible.

Note that most functions are randomized functions of Las Vegas type i.e. every answer is correct, but with small probability the algorithm fails to get an answer.

public == with

  completeEchelonBasis : (V V R) -> M R
  ++ completeEchelonBasis(lv) completes the basis lv assumed
  ++ to be in echelon form of a subspace of R**n (n the length
  ++ of all the vectors in lv with unit vectors to a basis of
  ++ R**n. It is assumed that the argument is not an empty
  ++ vector and that it is not the basis of the 0-subspace.
  ++ Note that the rows of the result correspond to the vectors
  ++ of the basis.
  createRandomElement : (L M R, M R) -> M R
  ++ createRandomElement(aG,x) creates a random element of the group
  ++ algebra generated by aG.
  -- randomWord : (L L I, L M) -> M R
  --++ You can create your own 'random' matrix with "randomWord(lli, lm)".
  --++ Each li in lli determines a product of matrices, the entries in li
  --++ determine which matrix from lm is chosen. Finally we sum over all
  --++ products. The result "sm" can be used to call split with (e.g.)
  --++ second parameter "first nullSpace sm"
  if R has EuclideanDomain then -- using rowEchelon
  cyclicSubmodule : (L M R, V R) -> V V R
  ++ cyclicSubmodule(lm,v) generates a basis as follows.
  ++ It is assumed that the size n of the vector equals the number
  ++ of rows and columns of the matrices. Then the matrices generate
  ++ a subalgebra, say \spad{A}, of the algebra of all square matrices of
  ++ dimension n. V R is an \spad{A}-module in the natural way.
+ cyclicSubmodule(lm,v) generates the R-Basis of Av as
+ described in section 6 of R. A. Parker's "The Meat-Axe".
+ Note that in contrast to the description in "The Meat-Axe" and to
+ standardBasisOfCyclicSubmodule the result is in echelon form.

standardBasisOfCyclicSubmodule : (L M R, V R) -> M R
+ standardBasisOfCyclicSubmodule(lm,v) returns a matrix as follows.
+ It is assumed that the size n of the vector equals the number
+ of rows and columns of the matrices. Then the matrices generate
+ a subalgebra, say \spad{A},
+ of the algebra of all square matrices of
+ dimension n. V R is an \spad{A}-module in the natural way.
+ standardBasisOfCyclicSubmodule(lm,v) calculates a matrix whose
+ non-zero column vectors are the R-Basis of Av achieved
+ in the way as described in section 6
+ of R. A. Parker's "The Meat-Axe".
+ Note that in contrast to cyclicSubmodule, the result is not
+ in echelon form.

if R has Field then -- only because of inverse in SM

areEquivalent? : (L M R, L M R, B, I) -> M R
+ areEquivalent?(aG0,aG1,randomelements,numberOfTries) tests
+ whether the two lists of matrices, all assumed of same
+ square shape, can be simultaneously conjugated by a non-singular
+ matrix. If these matrices represent the same group generators,
+ the representations are equivalent.
+ The algorithm tries
+ numberOfTries times to create elements in the
+ generated algebras in the same fashion. If their ranks differ,
+ they are not equivalent. If an
+ isomorphism is assumed, then
+ the kernel of an element of the first algebra
+ is mapped to the kernel of the corresponding element in the
+ second algebra. Now consider the one-dimensional ones.
+ If they generate the whole space (e.g. irreducibility !)
+ we use standardBasisOfCyclicSubmodule to create the
+ only possible transition matrix. The method checks whether the
+ matrix conjugates all corresponding matrices from aG1.
+ The way to choose the singular matrices is as in meatAxe.
+ If the two representations are equivalent, this routine
+ returns the transformation matrix TM with
+ aG0.i * TM = TM * aG1.i for all i. If the representations
+ are not equivalent, a small 0-matrix is returned.
+ Note that the case
+ with different sets of group generators cannot be handled.

areEquivalent? : (L M R, L M R) -> M R
+ areEquivalent?(aG0,aG1) calls areEquivalent?(aG0,aG1,true,25).
+ Note that the choice of 25 was rather arbitrary.

areEquivalent? : (L M R, L M R, I) -> M R
+ areEquivalent?(aG0,aG1,numberOfTries) calls
+ areEquivalent?(aG0,aG1,true,25).
+ Note that the choice of 25 was rather arbitrary.
isAbsolutelyIrreducible? : (L M R, I) -> B
++ isAbsolutelyIrreducible?(aG, numberOfTries) uses
++ Norton's irreducibility test to check for absolute
++ irreducibility, assuming if a one-dimensional kernel is found.
++ As no field extension changes create "new" elements
++ in a one-dimensional space, the criterium stays true
++ for every extension. The method looks for one-dimensionals only
++ by creating random elements (no fingerprints) since
++ a run of meatAxe would have proved absolute irreducibility
++ anyway.

isAbsolutelyIrreducible? : L M R -> B
++ isAbsolutelyIrreducible?(aG) calls
++ isAbsolutelyIrreducible?(aG,25).
++ Note that the choice of 25 was rather arbitrary.

split : (L M R, V R) -> L L M R
++ split(aG, vector) returns a subalgebra \spad{A} of all
++ square matrix of dimension n as a list of list of matrices,
++ generated by the list of matrices aG, where n denotes both
++ the size of vector as well as the dimension of each of the
++ square matrices.
++ V R is an A-module in the natural way.
++ split(aG, vector) then checks whether the cyclic submodule
++ generated by vector is a proper submodule of V R.
++ If successful, it returns a two-element list, which contains
++ first the list of the representations of the submodule,
++ then the list of the representations of the factor module.
++ If the vector generates the whole module, a one-element list
++ of the old representation is given.
++ Note that a later version this should call the other split.

split: (L M R, V V R) -> L L M R
++ split(aG,submodule) uses a proper submodule of R**n
++ to create the representations of the submodule and of
++ the factor module.

if (R has Finite) and (R has Field) then
meatAxe : (L M R, B, I, I) -> L L M R
++ meatAxe(aG,randomElements,numberOfTries, maxTests) returns
++ a 2-list of representations as follows.
++ All matrices of argument aG are assumed to be square
++ and of equal size.
++ Then \spad{A} generates a subalgebra, say \spad{A}, of the algebra
++ of all square matrices of dimension n. V R is an A-module
++ in the usual way.
++ meatAxe(aG,numberOfTries, maxTests) creates at most
++ numberOfTries random elements of the algebra, tests
++ then for singularity. If singular, it tries at most maxTests
++ elements of its kernel to generate a proper submodule.
++ If successful, a 2-list is returned: first, a list
++ containing first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module.
meatAxe : L M R -> L L M R
++ meatAxe(aG) calls meatAxe(aG,false,25,7) returns
++ a 2-list of representations as follows.
++ All matrices of argument \spad{aG} are assumed to be square
++ and of
++ equal size. Then \spad{aG} generates a subalgebra,
++ say \spad{A}, of the algebra
++ of all square matrices of dimension \( n \). \spad{V R} is an \spad{A}-module
++ in the usual way.
++ meatAxe(aG) creates at most 25 random elements
++ of the algebra, tests
++ them for singularity. If singular, it tries at most 7
++ elements of its kernel to generate a proper submodule.
++ If successful a list which contains first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module is returned.
++ Otherwise, if we know that all the kernel is already
++ scanned, Norton’s irreducibility test can be used either
++ to prove irreducibility or to find the splitting.
++ Notes: the first 6 tries use Parker’s fingerprints.
++ Also, 7 covers the case of three-dimensional kernels over
++ the field with 2 elements.

meatAxe: (L M R, B) -> L L M R
++ meatAxe(aG, randomElements) calls meatAxe(aG,false,6,7),
++ only using Parker’s fingerprints, if randomElemnts is false.
++ If it is true, it calls meatAxe(aG,true,25,7),
++ only using random elements.
++ Note that the choice of 25 was rather arbitrary.
++ Also, 7 covers the case of three-dimensional kernels over the field
++ with 2 elements.

meatAxe : (L M R, PI) -> L L M R
++ meatAxe(aG, numberOfTries) calls
++ meatAxe(aG,true,numberOfTries,7).
++ Notes: 7 covers the case of three-dimensional
++ kernels over the field with 2 elements.

scanOneDimSubspaces: (L V R, I) -> V R
++ scanOneDimSubspaces(basis,n) gives a canonical representative
++ of the \( n \)-th one-dimensional subspace of the vector space
++ generated by the elements of basis, all from \spad{R}**n.
++ The coefficients of the representative are of shape
++ \((0,\ldots,0,1,*\ldots,*)\), * in \spad{R}. If the size of \spad{R}
++ is \( q \), then there are \( (q**n-1)/(q-1) \) of them.
++ We first reduce \( n \) modulo this number, then find the
++ largest \( i \) such that \( +[q**i \text{ for } i \text{ in } 0..i-1] \leq n \).
++ Subtracting this sum of powers from \( n \) results in an
++ i-digit number to basis q. This fills the positions of the
++ stars.
-- would prefer to have (V V R,...) but nullSpace results
-- in L V R

coerce

--- package RESLATC ResolveLatticeCompletion ---

)abbrev package RESLATC ResolveLatticeCompletion
++ Author: Stephen M. Watt
++ Date Created: 1986
++ Date Last Updated: May 30, 1991
++ Description:
++ This package provides coercions for the special types \spadtype{Exit}
++ and \spadtype{Void}.

ResolveLatticeCompletion(S: Type): with
  coerce: S -> Void
      ++ coerce(s) throws all information about s away.
      ++ This coercion allows values of any type to appear
      ++ in contexts where they will not be used.
      ++ For example, it allows the resolution of different types in
      ++ the \spad{then} and \spad{else} branches when an \spad{if}
      ++ is in a context where the resulting value is not used.
  coerce: Exit -> S
      ++ coerce(e) is never really evaluated. This coercion is
      ++ used for formal type correctness when a function will not
      ++ return directly to its caller.

== add
  coerce(s: S): Void == void()
  coerce(e: Exit): S ==

RootsFindingPackage examples

This package finds all the roots of a polynomial. If the constant field is not large enough then it returns the list of found zeros and the degree of the extension need to find the other roots missing. If the return degree is 1 then all the roots have been found. If 0 is return for the extension degree then there are an infinite number of zeros, that is you ask for the zeros of 0. In the case of infinite field a list of all found zeros is kept and for each other call of a function that finds zeros, a check is made on that list; this is to keep a kind of "canonical" representation of the elements.

P== with

  distinguishedRootsOf: (SUP(K),K) -> REC
  ++ distinguishedRootsOf returns a record consisting of a list of zeros
  ++ of the input polynomial followed by the smallest extension degree
  ++ needed to find all the zeros. If K has
  ++ \spad{PseudoAlgebraicClosureOfFiniteFieldCategory} or
  ++ \spad{PseudoAlgebraicClosureOfRationalNumberCategory} then
  ++ a root is created for each irreducible factor, and only these
  ++ roots are returns and not their conjugate.

distinguishedCommonRootsOf: (List SUP(K),K) -> REC
  ++ distinguishedCommonRootsOf returns the common zeros of a list of
  ++ polynomial. It returns a record as in distinguishedRootsOf. If 0
  ++ is returned as extension degree then there are an infinite number
  ++ of common zeros (in this case, the polynomial 0 was given in the
  ++ list of input polynomials).

foundZeroes: () -> List K
  ++ foundZeroes returns the list of already
  ++ found zeros by the functions
  ++ distinguishedRootsOf and
  ++ distinguishedCommonRootsOf.

setFoundZeroes: List K -> List K
  ++ setFoundZeroes sets the list of foundZeroes to the given one.

package SRDCMPK SquareFreeRegularSetDecompositionPackage

SquareFreeRegularSetDecompositionPackage examples

A package providing a new algorithm for solving polynomial systems by means of regular chains. Two ways of solving are provided: in the sense of Zariski closure (like in Kalkbrener's algorithm) or in the sense of the regular zeros (like in Wu, Wang or Lazard-Moreno methods). This algorithm is valid for any type of regular set. It does not care about the way a polynomial is added in an regular set, or how two quasi-components are compared
(by an inclusion-test), or how the invertibility test is made in the tower of simple extensions associated with a regular set.

These operations are realized respectively by the domain TS and the packages QCMPPK(R,E,V,P,TS) and RSETGCD(R,E,V,P,TS).

The same way it does not care about the way univariate polynomial gcds (with coefficients in the tower of simple extensions associated with a regular set) are computed. The only requirement is that these gcds need to have invertible initials (normalized or not).

WARNING. There is no need for a user to call directly any operation of this package since they can be accessed by the domain \texttt{axiomType(TS)}. Thus, the operations of this package are not documented.

— package MATSTOR StorageEfficientMatrixOperations —

)abbrev package MATSTOR StorageEfficientMatrixOperations
++ Author: Clifton J. Williamson
++ Date Created: 18 July 1990
++ Date Last Updated: 18 July 1990
++ Description:
++ This package provides standard arithmetic operations on matrices.
++ The functions in this package store the results of computations
++ in existing matrices, rather than creating new matrices. This
++ package works only for matrices of type Matrix and uses the
++ internal representation of this type.

StorageEfficientMatrixOperations(R):Exports == Implementation where
  R : Ring
  M ==> Matrix R
  NNI ==> NonNegativeInteger
  ARR ==> PrimitiveArray R
  REP ==> PrimitiveArray PrimitiveArray R

Exports ==>

  copy_! : (M,M) -> M
  ++ \spad{copy!(c,a)} copies the matrix \spad{a} into the matrix c.
  ++ Error: if \spad{a} and c do not have the same
  ++ dimensions.

  plus_! : (M,M,M) -> M
  ++ \spad{plus!(c,a,b)} computes the matrix sum \spad{a + b} and stores the
  ++ result in the matrix c.
  ++ Error: if \spad{a}, b, and c do not have the same dimensions.

  minus_! : (M,M) -> M
  ++ \spad{minus!(c,a)} computes \spad{-a} and stores the result in the
++ matrix c.
++ Error: if a and c do not have the same dimensions.

minus_! : (M, M, M) -> M
++ \spad{\text{\texttt{minus!}}(c, a, b)} computes the matrix difference \spad{a - b}
++ and stores the result in the matrix c.
++ Error: if \spad{a}, b, and c do not have the same dimensions.

leftScalarTimes_! : (M, R, M) -> M
++ \spad{\text{\texttt{leftScalarTimes!}}(c, r, a)} computes the scalar product
++ \spad{r * a} and stores the result in the matrix c.
++ Error: if \spad{a} and c do not have the same dimensions.

rightScalarTimes_! : (M, M, R) -> M
++ \spad{\text{\texttt{rightScalarTimes!}}(c, a, r)} computes the scalar product
++ \spad{a * r} and stores the result in the matrix c.
++ Error: if \spad{a} and c do not have the same dimensions.

times_! : (M, M, M) -> M
++ \spad{\text{\texttt{times!}}(c, a, b)} computes the matrix product \spad{a * b}
++ and stores the result in the matrix c.
++ Error: if \spad{a}, b, and c do not have
++ compatible dimensions.

power_! : (M, M, M, M, NNI) -> M
++ \spad{\text{\texttt{power!}}(a, b, c, m, n)} computes \spad{m ** n} and stores the result in
++ \spad{a}. The matrices b and c are used to store intermediate results.
++ Error: if \spad{a}, b, c, and m are not square
++ and of the same dimensions.

"**" : (M, NNI) -> M
++ \spad{\text{\texttt{**}}(x, n)} computes the n-th power
++ of a square matrix. The power n is assumed greater than 1.

====================================================================
StreamTaylorSeriesOperations examples
====================================================================

StreamTaylorSeriesOperations implements Taylor series arithmetic,
where a Taylor series is represented by a stream of its coefficients.

Problems raising a UTS to a negative integer power.

The code in powern(rn,x) which raises an unnecessary error
where no distinction between rational and integer powers are made.

The fix is easy. Since the problem does not exist in SUPS we can
just take the definition there.

)abbrev package STTAYLOR StreamTaylorSeriesOperations
++ Author: William Burge, Stephen Watt, Clifton J. Williamson
++ Date Created: 1986
++ Date Last Updated: 26 May 1994
++ Description:
++ StreamTaylorSeriesOperations implements Taylor series arithmetic,
++ where a Taylor series is represented by a stream of its coefficients.

StreamTaylorSeriesOperations(A): Exports == Implementation where
  A : Ring
  RN ==> Fraction Integer
  I ==> Integer
  NNI ==> NonNegativeInteger
  ST ==> Stream
  SP2 ==> StreamFunctions2
  SP3 ==> StreamFunctions3
  L ==> List
  LA ==> List A
  YS ==> Y$ParadoxicalCombinatorsForStreams(A)
UN  ==>  Union(ST A,"failed")
Exports  ==>  with
  "+"  :  (ST A,ST A) -> ST A
++  \spad{a + b} returns the power series sum of \spad{a} and \spad{b}:
++  \spad{[a0,a1,...] + [b0,b1,...] = [a0 + b0,a1 + b1,...]}
"-"  :  (ST A,ST A) -> ST A
++  \spad{a - b} returns the power series difference of \spad{a} and
++  \spad{b}:
++  \spad{[a0,a1,...] - [b0,b1,...] = [a0 - b0,a1 - b1,...]}
"-"  :  ST A -> ST A
++  \spad{-a} returns the power series negative of \spad{a}:
++  \spad{-[a0,a1,...] = [-a0,-a1,...]}
"*"  :  (ST A,ST A) -> ST A
++  \spad{a * b} returns the power series (Cauchy) product of \spad{a} and \spad{b}:
++  \spad{[a0,a1,...] * [b0,b1,...] = [c0,c1,...]} where
++  \spad{c_k = \text{sum}(i + j = k, a_i * b_j)}.
"*"  :  (A,ST A) -> ST A
++  \spad{r * a} returns the power series scalar multiplication of \spad{r} by \spad{a}:
++  \spad{r * [a0,a1,...] = [r * a0,r * a1,...]}
"*"  :  (ST A,A) -> ST A
++  \spad{a * r} returns the power series scalar multiplication of \spad{a} by \spad{r}:
++  \spad{[a0,a1,...] * r = [a0 * r,a1 * r,...]}
"exquo"  :  (ST A,ST A) -> Union(ST A,"failed")
++  \spad{\text{exquo}(a,b)} returns the power series quotient of \spad{a} by \spad{b},
++  if the quotient exists, and "failed" otherwise
"/"  :  (ST A,ST A) -> ST A
++  \spad{a / b} returns the power series quotient of \spad{a} by \spad{b}.
++  An error message is returned if \spad{\text{exquo}(b)} is not invertible.
++  This function is used in fixed point computations.
recip  :  ST A -> UN
++  \spad{\text{recip}(a)} returns the power series reciprocal of \spad{a}, or
++  "failed" if not possible.
monom  :  (A,I) -> ST A
++  \spad{\text{monom}(deg,coef)} is a monomial of degree \spad{deg} with coefficient
++  \spad{coef}.
integers  :  I -> ST I
++  \spad{\text{integers}(n)} returns \spad{[n,n+1,n+2,...]}.
oddintegers  :  I -> ST I
++  \spad{\text{oddintegers}(n)} returns \spad{[n,n+2,n+4,...]}.
int  :  A -> ST A
++  \spad{\text{int}(r)} returns \spad{[r,r+1,r+2,...]}, where \spad{r} is a ring element.
mapmult  :  (ST A,ST A) -> ST A
++  \spad{\text{mapmult}([a0,a1,...],[b0,b1,...])}
++  returns \spad{[a0*b0,a1*b1,...]}.
deriv  :  ST A -> ST A
++  \spad{\text{deriv}(a)} returns the derivative of the power series with
++  respect to the power series variable. Thus
++  \spad{\text{deriv}([a0,a1,a2,...])} returns \spad{[a1,2 a2,3 a3,...]}.
gderiv  :  (I -> A,ST A) -> ST A
++  gderiv(f,[a0,a1,a2,...]) returns
++  \spad{[f(0)*a0,f(1)*a1,f(2)*a2,...]}. 
coerce : A -> ST A
++ coerce(r) converts a ring element r to a stream with one element.

eval : (ST A,A) -> ST A
++ \text{eval}(a,r) returns a stream of partial sums of the power series
++ \text{spad}(a) evaluated at the power series variable equal to r.

compose : (ST A,ST A) -> ST A
++ compose(a,b) composes the power series \text{spad}(a) with
++ the power series b.

lagrange : ST A -> ST A
++ lagrange(g) produces the power series for \( f \) where \( f \) is
++ implicitly defined as \text{spad}(f(z) = z*g(f(z))).

revert : ST A -> ST A
++ revert(a) computes the inverse of a power series \text{spad}(a)
++ with respect to composition.
++ the series should have constant coefficient 0 and first
++ order coefficient 1.

addiag : ST ST A -> ST A
++ addiag(x) performs diagonal addition of a stream of streams. if \( x = 
++ \text{spad}([[a<0,0>,a<0,1>,\ldots],[a<1,0>,a<1,1>,\ldots],[a<2,0>,a<2,1>,\ldots],\ldots]] 
++ and \text{spad}(addiag(x) = [b<0,b<1>,\ldots], then \( b<k> = \text{sum}(i+j=k,a<i,j>) \)).

lambert : ST A -> ST A
++ lambert(st) computes \text{spad}(f(x) + f(x^2) + f(x^3) + \ldots)
++ if \( st \) is a stream representing \text{spad}(f(x)).
++ This function is used for computing infinite products.
++ If \text{spad}(f(x)) is a power series with constant coefficient 1 then
++ \text{spad}(\text{prod}(f(x^n),n = 1..\infty) = \exp(\text{lambert}(\log(f(x))))).

oddlambert : ST A -> ST A
++ oddlambert(st) computes \text{spad}(f(x) + f(x^3) + f(x^5) + \ldots)
++ if \( st \) is a stream representing \text{spad}(f(x)).
++ This function is used for computing infinite products.
++ If \( f(x) \) is a power series with constant coefficient 1 then
++ \text{spad}(\text{prod}(f(x^{2n-1}),n=1..\infty) = \exp(\text{oddlambert}(\log(f(x))))).

evenlambert : ST A -> ST A
++ evenlambert(st) computes \text{spad}(f(x^2) + f(x^4) + f(x^6) + \ldots)
++ if \( st \) is a stream representing \text{spad}(f(x)).
++ This function is used for computing infinite products.
++ If \text{spad}(f(x)) is a power series with constant coefficient 1, then
++ \text{spad}(\text{prod}(f(x^{2n}),n=1..\infty) = \exp(\text{evenlambert}(\log(f(x))))).

generalLambert : (ST A,I,I) -> ST A
++ generalLambert(f(x),a,d) returns
++ \text{spad}(f(x^a) + f(x^{a+d}) + f(x^{a+2d}) + \ldots).
++ \text{spad}(f(x)) should have zero constant
++ coefficient and \text{spad}(a) and d should be positive.

multisect : (I,I,ST A) -> ST A
++ multisect(a,b,st)
++ selects the coefficients of \text{spad}(x**(a+b)*n+a),
++ and changes them to \text{spad}(x**n).

invmultisect : (I,I,ST A) -> ST A
++ invmultisect(a,b,st) substitutes \text{spad}(x**(a+b)*n) for \text{spad}(x**n)
++ and multiplies by \text{spad}(x**b).
if A has Algebra RN then
integrate : (A,ST A) -> ST A
++ integrate(r,a) returns the integral of the power series \(a\)
++ with respect to the power series variable integration where
++ r denotes the constant of integration. Thus
++ \(\int (a,[a_0,a_1,a_2,\ldots]) = [a,a_0,a_1/2,a_2/3,\ldots]\).
lazyIntegrate : (A,() -> ST A) -> ST A
++ lazyIntegrate(r,f) is a local function
++ used for fixed point computations.
lazyIntegrate : (A,() -> ST A) -> ST A
++ lazyIntegrate(r,f) is a local function
++ used for fixed point computations.

if A has Field then
mapdiv : (ST A,ST A) -> ST A
++ mapdiv([a0,a1,\ldots],[b0,b1,\ldots]) returns
++ \(\frac{a_0}{b_0},\frac{a_1}{b_1},\ldots\).
lazyGintegrate : (I -> A,A,() -> ST A) -> ST A
++ lazyGintegrate(f,r,g) is used for fixed point computations.
power : (A,ST A) -> ST A
++ power(a,f) returns the power series f raised to the power \(a\).

   ++ log(st) computes the log of a power series.
   "**" : (ST,ST) -> ST
   ++ st1 ** st2 computes the power of a power series st1 by another
   ++ power series st2.
--% TrigonometricFunctionCategory
sin : ST -> ST
++ sin(st) computes sine of a power series st.
cos : ST -> ST
++ cos(st) computes cosine of a power series st.
tan : ST -> ST
++ tan(st) computes tangent of a power series st.
cot : ST -> ST
++ cot(st) computes cotangent of a power series st.
sec : ST -> ST
++ sec(st) computes secant of a power series st.
csc : ST -> ST
++ csc(st) computes cosecant of a power series st.

asin : ST -> ST
++ asin(st) computes arcsine of a power series st.
acos : ST -> ST
++ acos(st) computes arccosine of a power series st.
atan : ST -> ST
++ atan(st) computes arctangent of a power series st.
acot : ST -> ST
++ acot(st) computes arccotangent of a power series st.

asec : ST -> ST
++ asec(st) computes arcsecant of a power series st.
acsc : ST -> ST
++ acsc(st) computes arccosecant of a power series st.

--% HyperbolicTrigonometricFunctionCategory
sinh : ST -> ST
++ sinh(st) computes the hyperbolic sine of a power series st.
cosh : ST -> ST
++ cosh(st) computes the hyperbolic cosine of a power series st.
tanh : ST -> ST
++ tanh(st) computes the hyperbolic tangent of a power series st.
coth : ST -> ST
++ coth(st) computes the hyperbolic cotangent of a power series st.

sech : ST -> ST
++ sech(st) computes the hyperbolic secant of a power series st.
csch : ST -> ST
++ csch(st) computes the hyperbolic cosecant of a power series st.
asinh : ST -> ST
++ asinh(st) computes the inverse hyperbolic sine of a power series st.
acosh : ST -> ST
++ acosh(st) computes the inverse hyperbolic cosine of a power series st.

atanh : ST -> ST
++ atanh(st) computes the inverse hyperbolic tangent of a power series st.
acoth : ST -> ST
++ acoth(st) computes the inverse hyperbolic cotangent of a power series st.
asech : ST -> ST
++ asech(st) computes the inverse hyperbolic secant of a
++ power series st.

acsch : ST -> ST
++ acsch(st) computes the inverse hyperbolic
++ cosecant of a power series st.

++ Authors: J. Grabmeier
++ Date Created: 02 April 1992
++ Date Last Updated: 14 April 1992
++ Description:
++ StructuralConstantsPackage provides functions creating
++ structural constants from a multiplication tables or a basis
++ of a matrix algebra and other useful functions in this context.

StructuralConstantsPackage(R:Field): public == private where

L == List
S == Symbol
FRAC == Fraction
POLY == Polynomial
V == Vector
M == Matrix
REC == Record(particular: Union(V R,"failed"),basis: List V R)
LSMP == LinearSystemMatrixPackage(R,V R,V R, M R)

public ==> with
  -- what we really want to have here is a matrix over
-- linear polynomials in the list of symbols, having arbitrary
-- coefficients from a ring extension of R, e.g. FRAC POLY R.
structuralConstants : (L S, M FRAC POLY R) -> V M FRAC POLY R
  ++ structuralConstants(ls,mt) determines the structural constants
  ++ of an algebra with generators ls and multiplication table mt, the
  ++ entries of which must be given as linear polynomials in the
  ++ indeterminates given by ls. The result is in particular useful
  ++ as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}
  ++ and \spadtype{GenericNonAssociativeAlgebra}.
structuralConstants : (L S, M POLY R) -> V M POLY R
  ++ structuralConstants(ls,mt) determines the structural constants
  ++ of an algebra with generators ls and multiplication table mt, the
  ++ entries of which must be given as linear polynomials in the
  ++ indeterminates given by ls. The result is in particular useful
  ++ as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}
  ++ and \spadtype{GenericNonAssociativeAlgebra}.
structuralConstants: L M R -> V M R
  ++ structuralConstants(basis) takes the basis of a matrix
  ++ algebra, e.g. the result of \spadfun{basisOfCentroid} and calculates
  ++ the structural constants.
  ++ Note, that the it is not checked, whether basis really is a
  ++ basis of a matrix algebra.
coordinates: (M R, L M R) -> V R
  ++ coordinates(a,[v1,...,vn]) returns the coordinates of \spad{a}
  ++ with respect to the \spad{R}-module basis \spad{v1},...,\spad{vn}.

SystemSolvePackage examples
====================================================================

Symbolic solver for systems of rational functions with coefficients in an integral domain R.

The systems are solved in the field of rational functions over R. Solutions are exact of the form variable = value when the value is a member of the coefficient domain R. Otherwise the solutions are implicitly expressed as roots of univariate polynomial equations over R.

Care is taken to guarantee that the denominators of the input equations do not vanish on the solution sets.

The arguments to solve can either be given as equations or as rational functions interpreted as equal to zero. The user can specify an explicit list of symbols to be solved for, treating all other symbols appearing as parameters or omit the list of symbols in which case the system tries to solve with respect to all symbols appearing in the input.

Cat == with
solve: (L F, L SE) -> L L EQ F
++ solve(lp,lv) finds the solutions of the list lp of
++ rational functions with respect to the list of symbols lv.

solve: (L EQ F, L SE) -> L L EQ F
++ solve(le,lv) finds the solutions of the
++ list le of equations of rational functions
++ with respect to the list of symbols lv.

solve: L F -> L L EQ F
++ solve(lp) finds the solutions of the list lp of rational
++ functions with respect to all symbols appearing in lp.

solve: L EQ F -> L L EQ F
++ solve(le) finds the solutions of the list le of equations of
++ rational functions with respect to all symbols appearing in le.

solve: (F, SE) -> L EQ F
++ solve(p,v) solves the equation p=0, where p is a rational function
++ with respect to the variable v.

solve: (EQ F,SE) -> L EQ F
++ solve(eq,v) finds the solutions of the equation
++ eq with respect to the variable v.

solve: F -> L EQ F
++ solve(p) finds the solution of a rational function p = 0
++ with respect to the unique variable appearing in p.

solve: EQ F -> L EQ F
++ solve(eq) finds the solutions of the equation eq
++ with respect to the unique variable appearing in eq.

triangularSystems: (L F, L SE) -> L L P R
++ triangularSystems(lf,lv) solves the system of equations
++ defined by lf with respect to the list of symbols lv;
++ the system of equations is obtaining
++ by equating to zero the list of rational functions lf.
++ The output is a list of solutions where
++ each solution is expressed as a "reduced" triangular system of
++ polynomials.

public ==> with

-- IS THERE A WORKING DOMAIN Tableau ??
-- coerce : M I -> Tableau(I)
--   ++ coerce(ytab) coerces the Young-Tableau ytab to an element of
--   ++ the domain Tableau(I).

coleman : (L I, L I, L I) -> M I
++ coleman(alpha,beta,pi):
   ++ there is a bijection from the set of matrices having nonnegative
   ++ entries and row sums alpha, column sums beta
   ++ to the set of Salpha - Sbeta double cosets of the
   ++ symmetric group Sn. (Salpha is the Young subgroup
   ++ corresponding to the improper partition alpha).
   ++ For a representing element pi of such a double coset,
   ++ coleman(alpha,beta,pi) generates the Coleman-matrix
   ++ corresponding to alpha, beta, pi.
   ++ Note that The permutation pi of \{1,2,...,n\} has to be given
   ++ in list form.
   ++ Note that the inverse of this map is inverseColeman
   ++ (if pi is the lexicographical smallest permutation
   ++ in the coset). For details see James/Kerber.

inverseColeman : (L I, L I, M I) -> L I
++ inverseColeman(alpha,beta,C):
   ++ there is a bijection from the set of matrices having nonnegative
   ++ entries and row sums alpha, column sums beta
   ++ to the set of Salpha - Sbeta double cosets of the
   ++ symmetric group Sn. (Salpha is the Young subgroup
   ++ corresponding to the improper partition alpha).
   ++ For such a matrix C, inverseColeman(alpha,beta,C)
++ calculates the lexicographical smallest $\pi$ in the
++ corresponding double coset.
++ Note that the resulting permutation $\pi$ of $\{1,2,...,n\}$
++ is given in list form.
++ Notes: the inverse of this map is coleman.
++ For details, see James/Kerber.
listYoungTableaus : (L I) -> L M I
++ listYoungTableaus($\lambda$) where $\lambda$ is a proper partition
++ generates the list of all standard tableaux of shape $\lambda$
++ by means of lattice permutations. The numbers of the lattice
++ permutation are interpreted as column labels. Hence the
++ contents of these lattice permutations are the conjugate of
++ $\lambda$.
++ Notes: the functions nextLatticePermutation and
++ makeYoungTableau are used.
++ The entries are from $0,...,n-1$.
makeYoungTableau : (L I,L I) -> M I
++ makeYoungTableau($\lambda$,gitter) computes for a given lattice
++ permutation gitter and for an improper partition $\lambda$
++ the corresponding standard tableau of shape $\lambda$.
++ Notes: see listYoungTableaus.
++ The entries are from $0,...,n-1$.
nextColeman : (L I, L I, M I) -> M I
++ nextColeman($\alpha$,$\beta$,C) generates the next Coleman matrix
++ of column sums $\alpha$ and row sums $\beta$ according
++ to the lexicographical order from bottom-to-top.
++ The first Coleman matrix is achieved by C=new(1,1,0).
++ Also, new(1,1,0) indicates that C is the last Coleman matrix.
nextLatticePermutation : (L I, L I, B) -> L I
++ nextLatticePermutation($\lambda$,lattP,constructNotFirst) generates
++ the lattice permutation according to the proper partition
++ $\lambda$ succeeding the lattice permutation lattP in
++ lexicographical order as long as constructNotFirst is true.
++ If constructNotFirst is false, the first lattice permutation
++ is returned.
++ The result nil indicates that lattP has no successor.
nextPartition : (V I, V I, I) -> V I
++ nextPartition($\gamma$,part,number) generates the partition of
++ number which follows part according to the right-to-left
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ $\gamma$. The first partition is achieved by part=[].
++ Also, [] indicates that part is the last partition.
nextPartition : (L I, V I, I) -> V I
++ nextPartition($\gamma$,part,number) generates the partition of
++ number which follows part according to the right-to-left
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ $\gamma$. the first partition is achieved by part=[].
++ Also, [] indicates that part is the last partition.
numberOfImproperPartitions: (I,I) -> I
  ++ numberOfImproperPartitions(n,m) computes the number of partitions
  ++ of the nonnegative integer n in m nonnegative parts with regarding
  ++ the order (improper partitions).
  ++ Example: numberOfImproperPartitions (3,3) is 10,
  ++ since [0,0,3], [0,1,2], [0,2,1], [0,3,0], [1,0,2], [1,1,1],
  ++ [1,2,0], [2,0,1], [2,1,0], [3,0,0] are the possibilities.
  ++ Note that this operation has a recursive implementation.

subSet : (I,I,I) -> L I
  ++ subSet(n,m,k) calculates the k-th m-subset of the set
  ++ 0,1,...,(n-1) in the lexicographic order considered as
  ++ a decreasing map from 0,...,(m-1) into 0,...,(n-1).
  ++ See S.G. Williamson: Theorem 1.60.
  ++ Error: if not (0 <= m <= n and 0 <= k < (n choose m)).

unrankImproperPartitions0 : (I,I,I) -> L I
  ++ unrankImproperPartitions(n,m,k) computes the k-th improper
  ++ partition of nonnegative n in m nonnegative parts in reverse
  ++ lexicographical order.
  ++ Example: [0,0,3] < [0,1,2] < [0,2,1] < [0,3,0] <
  ++ [1,0,2] < [1,1,1] < [1,2,0] < [2,0,1] < [2,1,0] < [3,0,0].
  ++ Error: if k is negative or too big.
  ++ Note that counting of subtrees is done by
  ++ numberOfImproperPartitions

unrankImproperPartitions1: (I,I,I) -> L I
  ++ unrankImproperPartitions1(n,m,k) computes the k-th improper
  ++ partition of nonnegative n in at most m nonnegative parts
  ++ ordered as follows: first, in reverse
  ++ lexicographically according to their non-zero parts, then
  ++ according to their positions (i.e. lexicographical order
  ++ using subSet: [3,0,0] < [0,3,0] < [0,0,3] < [2,1,0] <
  ++ [2,0,1] < [0,2,1] < [1,2,0] < [1,0,2] < [0,1,2] < [1,1,1].
  ++ Note that counting of subtrees is done by
  ++ numberOfImproperPartitionsInternal.

--- TaylorSolve.help ---

====================================================================
TaylorSolve examples
====================================================================

UTSSOL is a facility to compute the first few coefficients of a Taylor
series given only implicitly by a function f that vanishes when applied to
the Taylor series.

It uses the method of undetermined coefficients.

Could I either
take a function UTSCAT F $\rightarrow$ UTSCAT F and still be able to compute
with undetermined coefficients, or
take a function F $\rightarrow$ F, and do likewise?

Let's see.

Try to compute the equation without resorting to power series. I.e., $c$:

\[ c: \text{SUP SUP F}, \text{ and } f: \text{SUP SUP F } \rightarrow \text{SUP SUP F}. \]

Won't this make the computation of coefficients terribly slow?

I could also try to replace transcendental kernels with variables\dots

Unfortunately, SUP F does not have TRANFUN -- well, it can't, of
course. However, I'd like to be able to compute

\[ \sin(1+\text{monomial}(1,1)$\text{SUP SUP EXPR INT}). \]

\getchunk{implementation: UTSSOL TaylorSolve}

— implementation: UTSSOL TaylorSolve —

seriesSolve(f, l) ==
c1 :=
  map((x:F):SUP F +-> x::(SUP F), l)
  $ListFunctions2(F, SUP F)::(Stream SUP F)
coeffs: Stream SUP F := concat(c1, generate(monomial(1$F,1$NNI)))
--
coeffs: Stream SUP F := concat(c1, monomial(1$F,1$NNI))

\getchunk{implementation: UTSSOL TaylorSolve}
coeffs is the stream of the already computed coefficients of the solution, plus one which is so far undetermined. We store in st.2 the complete stream and in st.1 the stream starting with the first coefficient that has possibly not yet been computed.

The mathematics is not quite worked out. If coeffs is initialized as stream with all coefficients set to the \textit{same} transcendental value, and not enough initial values are given, then the missing ones are implicitly assumed to be all identical. It may well happen that a solution is produced, although it is not uniquely determined.

---

\textbf{implementation: UTSSOL TaylorSolve} ---

\texttt{st: List Stream SUP F := [coeffs, coeffs]}

Consider an arbitrary equation $f(x, y(x)) = 0$. When setting $x = 0$, we obtain $f(0, y(0)) = 0$. It is not necessarily the case that this determines $y(0)$ uniquely, so we need one initial value that satisfies this equation.

\texttt{seriesSolve} should check that the given initial values satisfy $f(0, y(0), y'(0), \ldots) = 0$.

Now consider the derivatives of $f$, where we write $y$ instead of $y(x)$ for better readability:

\[
\frac{d}{dx} f(x, y) = f_1(x, y) + f_2(x, y)y'
\]

and

\[
\frac{d^2}{dx^2} f(x, y) = f_{1,1}(x, y) + f_{1,2}(x, y)y' + f_{2,1}(x, y)y'' + f_{2,2}(x, y)(y')^2 + f_2(x, y)y''.
\]

In general, $\frac{d^2}{dx^2} f(x, y)$ depends only linearly on $y''$.

This points to another possibility: Since we know that we only need to solve linear equations, we could compute two values and then use interpolation. This might be a bit slower, but more importantly: can we still check that we have enough initial values? Furthermore, we then really need that \$f\$ is analytic, i.e., operators are not necessarily allowed anymore. However, it seems that composition is allowed.

---

\textbf{implementation: UTSSOL TaylorSolve} ---
If the next element was already calculated, we can simply return it:

— implementation: UTSSOL TaylorSolve —

then
    res := ground coeff
    st.1 := rest nr
else

Otherwise, we have to find the first non-satisfied relation and solve it. It should be linear, or a single non-constant monomial. That is, the solution should be unique.

— implementation: UTSSOL TaylorSolve —

ns := st.2
eqs: Stream SUP F := coefficients f series ns
while zero? first eqs repeat eqs := rest eqs
    eq: SUP F := first eqs
    if degree eq > 1 then
        if monomial? eq then res := 0
        else
            output(hconcat("The equation is: ", eq::OutputForm))
            $OutputPackage
            error "seriesSolve: equation for coefficient not linear"
        else res := (-coefficient(eq, 0$NNI)$(SUP F)
                      /coefficient(eq, 1$NNI)$(SUP F))
    nr.1 := res::SUP F
    --
    concat!(st.2, monomial(1$F,1$NNI))
    st.1 := rest nr

  ++ compile package.

Implementation ==> add

I have had to work my way around the following bug in the compiler: When a local variable
is given a mapping as a value, e.g.

foo : SF -> SF := makeFloatFunction(f,t),

the compiler cannot distinguish that local variable from a local function defined elsewhere
in the package. Thus, when 'foo' is passed to a function, e.g.

bird := fcn(foo),

foo will often be compiled as DRAW:foo rather than foo. This, of course, causes a run-time
error.

To avoid this problem, local variables are not given mappings as values, but rather (singleton)
lists of mappings. The first element of the list can always be extracted and everything
goes through as before. There is no major loss in efficiency, as the computation of points
will always dominate the computation time.

— package TRMANIP TranscendentalManipulations —

)abbrev package TRMANIP TranscendentalManipulations
++ Author: Bob Sutor, Manuel Bronstein
++ Date Created: Way back
++ Date Last Updated: 22 January 1996, added simplifyLog MCD.
++ Description:
++ TranscendentalManipulations provides functions to simplify and
++ expand expressions involving transcendental operators.

TranscendentalManipulations(R, F): Exports == Implementation where
R : Join(OrderedSet, GcdDomain)
F : Join(FunctionSpace R, TranscendentalFunctionCategory)

Z ==> Integer
K ==> Kernel F
P  ==> SparseMultivariatePolynomial(R, K)
UP ==> SparseUnivariatePolynomial P
POW ==> "%power"::Symbol
PRODUCT ==> Record(coef : Z, var : K)
FPR ==> Fraction Polynomial R

Exports ==> with
expand : F -> F
++ expand(f) performs the following expansions on f:\begin{items}
++ \item 1. logs of products are expanded into sums of logs,
++ \item 2. trigonometric and hyperbolic trigonometric functions
++ of sums are expanded into sums of products of trigonometric
++ and hyperbolic trigonometric functions.
++ \item 3. formal powers of the form \spad{(a/b)**c} are expanded into
++ \spad{a**c * b**(-c)}.
++ \end{items}
simplify : F -> F
++ simplify(f) performs the following simplifications on f:\begin{items}
++ \item 1. rewrites trigs and hyperbolic trigs in terms
++ of \spad{\sin}, \spad{\cos}, \spad{\sinh}, \spad{\cosh}.
++ \item 2. rewrites \spad{\sin**2} and \spad{\sinh**2} in terms
++ of \spad{cos} and \spad{cosh},
++ item 3. rewrites \spad{exp(a)*exp(b)} as \spad{exp(a+b)}.
++ item 4. rewrites \spad{(a**(1/n))**m * (a**(1/s))**t} as a single
++ power of a single radical of \spad{a}.
++ \end{items}

htrigs : F -> F
++ htrigs(f) converts all the exponentials in f into
++ hyperbolic sines and cosines.
simplifyExp: F -> F
++ simplifyExp(f) converts every product \spad{exp(a)*exp(b)}
++ appearing in f into \spad{exp(a+b)}.
simplifyLog : F -> F
++ simplifyLog(f) converts every \spad{log(a) - log(b)} appearing in f
++ into \spad{log(a/b)}, every \spad{log(a) + log(b)} into \spad{log(a*b)}
++ and every \spad{n*log(a)} into \spad{log(a^n)}.

expandPower: F -> F
++ expandPower(f) converts every power \spad{(a/b)**c} appearing
++ in f into \spad{a**c * b**(-c)}.

expandLog : F -> F
++ expandLog(f) converts every \spad{log(a) - log(b)} appearing in f
++ into \spad{log(a/b)}, and every \spad{log(a*b)} into
++ \spad{log(a) + log(b)}.

++ cos2sec(f) converts every \spad{cos(u)} appearing in f into
++ \spad{1/sec(u)}.

cosh2sech : F -> F
++ cosh2sech(f) converts every \spad{cosh(u)} appearing in f into
++ \spad{1/sech(u)}.
cot2trig : F -> F
++ cot2trig(f) converts every \spad{cot(u)} appearing in f into
++ \spad{cos(u)/sin(u)}.

++ coth2trigh(f) converts every \spad{coth(u)} appearing in f into
++ \spad{cosh(u)/sinh(u)}.

csc2sin : F -> F
++ csc2sin(f) converts every \spad{csc(u)} appearing in f into
++ \spad{1/sin(u)}.

csch2sinh : F -> F
++ csch2sinh(f) converts every \spad{csch(u)} appearing in f into
++ \spad{1/sinh(u)}.

sec2cos : F -> F
++ sec2cos(f) converts every \spad{sec(u)} appearing in f into
++ \spad{1/cos(u)}.

sech2cosh : F -> F
++ sech2cosh(f) converts every \spad{sech(u)} appearing in f into
++ \spad{1/cosh(u)}.

++ sin2csc(f) converts every \spad{sin(u)} appearing in f into
++ \spad{1/csc(u)}.

sinh2csch : F -> F
++ sinh2csch(f) converts every \(\text{spad}\{\sinh(u)\}\) appearing in \(f\) into
++ \(\text{spad}\{1/\csc(u)\}\).

\text{tan2trig} : F \to F
++ \text{tan2trig}(f) converts every \(\text{spad}\{\tan(u)\}\) appearing in \(f\) into
++ \(\text{spad}\{\sin(u)/\cos(u)\}\).

\text{tanh2trigh} : F \to F
++ \text{tanh2trigh}(f) converts every \(\text{spad}\{\tanh(u)\}\) appearing in \(f\) into
++ \(\text{spad}\{\sinh(u)/\cosh(u)\}\).

\text{tan2cot} : F \to F
++ \text{tan2cot}(f) converts every \(\text{spad}\{\tan(u)\}\) appearing in \(f\) into
++ \(\text{spad}\{1/\cot(u)\}\).

\text{tanh2coth} : F \to F
++ \text{tanh2coth}(f) converts every \(\text{spad}\{\tanh(u)\}\) appearing in \(f\) into
++ \(\text{spad}\{1/\coth(u)\}\).

\text{cot2tan} : F \to F
++ \text{cot2tan}(f) converts every \(\text{spad}\{\cot(u)\}\) appearing in \(f\) into
++ \(\text{spad}\{1/\tan(u)\}\).

\text{coth2tanh} : F \to F
++ \text{coth2tanh}(f) converts every \(\text{spad}\{\coth(u)\}\) appearing in \(f\) into
++ \(\text{spad}\{1/\tanh(u)\}\).

\text{removeCosSq} : F \to F
++ \text{removeCosSq}(f) converts every \(\text{spad}\{\cos(u)**2\}\) appearing in \(f\) into
++ \(\text{spad}\{1 - \sin(x)**2\}\), and also reduces higher
++ powers of \(\text{spad}\{\cos(u)\}\) with that formula.

\text{removeSinSq} : F \to F
++ \text{removeSinSq}(f) converts every \(\text{spad}\{\sin(u)**2\}\) appearing in \(f\) into
++ \(\text{spad}\{1 - \cos(x)**2\}\), and also reduces higher powers of
++ \(\text{spad}\{\sin(u)\}\) with that formula.

\text{removeCoshSq} : F \to F
++ \text{removeCoshSq}(f) converts every \(\text{spad}\{\cosh(u)**2\}\) appearing in \(f\) into
++ \(\text{spad}\{1 - \sinh(x)**2\}\), and also reduces higher powers of
++ \(\text{spad}\{\cosh(u)\}\) with that formula.

\text{removeSinhSq} : F \to F
++ \text{removeSinhSq}(f) converts every \(\text{spad}\{\sinh(u)**2\}\) appearing in \(f\) into
++ \(\text{spad}\{1 - \cosh(x)**2\}\), and also reduces higher powers
++ of \(\text{spad}\{\sinh(u)\}\) with that formula.

\text{if} \(R\) has \text{PatternMatchable}(R) and \(R\) has \text{ConvertibleTo}(\text{Pattern}(R))
and \(F\) has \text{ConvertibleTo}(\text{Pattern}(R)) and \(F\) has \text{PatternMatchable} \(R\) then
\text{expandTrigProducts} : F \to F
++ \text{expandTrigProducts}(e) replaces \(\text{axiom}\{\sin(x)\ast\sin(y)\}\) by
++ \(\text{spad}\{\cos(x-y)\ast\cos(x+y)/2\}\), \(\text{axiom}\{\cos(x)\ast\cos(y)\}\) by
++ \(\text{spad}\{\cos(x-y)\ast\cos(x+y)/2\}\), and \(\text{axiom}\{\sin(x)\ast\cos(y)\}\) by
++ \(\text{spad}\{\sin(x-y)\ast\sin(x+y)/2\}\). Note that this operation uses
++ the pattern matcher and so is relatively expensive. To avoid
++ getting into an infinite loop the transformations are applied
++ at most ten times.

The htrigs function

The htrigs function can be used to replace and reduce hyperbolic trigonometric identities. The identity for \( \sinh(x) \) is \( \frac{\exp(x) - \exp(-x)}{2} \). If we difference these we should get zero.

\[
\begin{align*}
  f &:= \sinh(x) - \frac{\exp(x) - \exp(-x)}{2} \\
  x &- x \\
  2\sinh(x) - \frac{\exp(x) + \exp(-x)}{2} \quad \text{---------------------} \\
  &\text{2}
\end{align*}
\]

The function htrigs(f) gives 0.

This works as follows:

\[
\text{m:=mainKernel } f \Rightarrow \sinh(x) \\
\text{Type: Union(Kernel(Expression(Integer))),...}
\]

which is coerced to the first part of the union:
k := m \cdot \text{Kernel(Expression(Integer))}

and the operator is extracted:

\text{op} := \text{operator}(k) \Rightarrow \sinh

\text{Type: BasicOperator}

The argument function extracts the variable used as arguments:

\text{argument } k \Rightarrow [x]

\text{Type Kernel(Expression(Integer))}

At this point we have picked apart the main Kernel into its operator and its arguments. We now process the list of arguments.

The function \text{htrigs} is called on every element of the argument list, which in this case, returns a list:

\text{arg} := [\text{htrigs } x \text{ for } x \text{ in argument } k] \Rightarrow [x]

\text{Type: List(Expression(Integer))}

We form a polynomial by replacing the kernel in the numerator with ?

\text{num} := \text{univariate(numer } f, k)

\begin{align*}
x & \quad -x \\
2? & \quad -e + e
\end{align*}

\text{Type: SparseUnivariatePolynomial(}
\begin{align*}
\text{SparseMultivariatePolynomial(}
\text{Integer, Kernel(Expression(Integer))))}
\end{align*}

and a polynomial of the denominator, replacing the kernel

\text{den} := \text{univariate(denom } f, k)

\begin{align*}
2
\end{align*}

\text{Type: SparseUnivariatePolynomial(}
\begin{align*}
\text{SparseMultivariatePolynomial(}
\text{Integer, Kernel(Expression(Integer))))}
\end{align*}

In this case the op is not the exponential so we are doing straight trig substitution. We reconstruct the function call using the op and arg values, that is:

\text{g1} := \text{op arg} \Rightarrow \sinh(x)

\text{Type: Expression(Integer)}

So \text{sup2htrigs}, which is a local function, is used to simplify the parts of the fraction. In this case,
sup2htrigs(num, g1:= op arg) ==> 0  
Type: Expression(Integer)

sup2htrigs(den, g1) ==> 2  
Type: Expression(Integer)

Thus, the result is 0

The identity for \(\cosh(x)\) is \((\exp(x) + \exp(-x))/2\)

If we difference these we should get zero

\[ f := \cosh(x) - (\exp^x + \exp^{-x})/2 \]

instead, by default, we get

\[
\frac{\exp^x - \exp^{-x}}{2} + 2\cosh(x)
\]

and the function call \(htrigs(f)\) gives 0

This works as follows:

\[ m:=\text{mainKernel} \rightarrow \exp \]

\[ k:=m::\text{Kernel(Integer)} \rightarrow \exp \]

and the operator is extracted:

\[ \text{op}:=\text{operator}(k) \rightarrow \exp \]

The argument function extracts the variable used as arguments:

\[ \text{argument} k \rightarrow [x] \]

At this point we have picked apart the main Kernel into its operator and its arguments. We now process the list of arguments.

The htrigs function is called on every element of the argument list, which in this case, returns a list:
arg:=[htrigs x for x in argument k]$List(Expression(Integer))
 => [x]
Type: List(Expression(Integer))

We form polynomial by replacing the kernel in the numerator with ?

num := univariate(numer f, k)

- x
- ? - %e + 2cosh(x)
Type: SparseUnivariatePolynomial(SparseMultivariatePolynomial(Integer, Kernel(Expression(Integer))))

and a polynomial of the denominator, replacing the kernel

den := univariate(denom f, k)

2
Type: SparseUnivariatePolynomial(SparseMultivariatePolynomial(Integer, Kernel(Expression(Integer))))

In this case, the expression

is?(op, "exp":Symbol) => true

so we form

a := first arg => x
Type: Expression(Integer)

since we know that

x

\cosh(x)+\sinh(x) => %e

we can form this use this expression in substitutions

g1 := \cosh(a)+\sinh(a) => \sinh(x)+\cosh(x)
Type: Expression(Integer)

since we know that

- x

\cosh(x)-\sinh(x) => - %e

we can form this use this expression in substitutions
g2 := cosh(a) - sinh(a) => -sinh(x) + cosh(x)
  Type: Expression(Integer)

b := (degree num)::Integer quo 2 => 0
  Type: NonNegativeInteger

The supexp function is using the g1 and g2 identities to replace exp(x)

supexp(num, g1, g2, b) => sinh(x) - cosh(x) - sinh(x) + 2cosh(x) - cosh(x)
  Type: Expression(Integer)

supexp(den, g1, g2, b) => 2
  Type: Expression(Integer)

which is effectively

t1/t2 => (sinh(x) - cosh(x) - sinh(x) + 2cosh(x) - cosh(x))/2
  Type: Expression(Integer)

the last form of which can be rearranged as:

(sinh(x) - sinh(x) + 2cosh(x) - cosh(x) - cosh(x))/2 => 0

so the result is 0

++ Author: Manuel Bronstein
++ Date Created: 17 August 1992
++ Date Last Updated: 3 February 1994
++ Description:
++ Risch differential equation system, transcendental case.

TranscendentalRischDESystem(F, UP): Exports == Implementation where
  F : Join(Field, CharacteristicZero, RetractableTo Integer)
  UP : UnivariatePolynomialCategory F

N  ==> NonNegativeInteger
Z  ==> Integer
RF ==> Fraction UP
V  ==> Vector UP
U  ==> Union(List UP, "failed")
REC ==> Record(z1:UP, z2:UP, r1:UP, r2:UP)

Exports ==> with

  monomRDEsys: (RF, RF, RF, UP -> UP) -> Union(Record(a:UP, b:RF, h:UP, c1:RF, c2:RF, t:UP), "failed")
  ++ monomRDEsys(f,g1,g2,D) returns \spad{\{A, B, H, C1, C2, T\}} such that
  ++ \spad{\{y_1', y_2'\} + ((0, -f), (f, 0)) (y_1, y_2) = (g_1, g_2)} has a solution
  ++ if and only if \spad{y_1 = Q_1 / T, y_2 = Q_2 / T},
  ++ where \spad{\{B, C1, C2, Q1, Q2\}} have no normal poles and satisfy
  ++ \spad{A \{Q_1', Q_2'\} + ((H, -B), (B, H)) \{Q_1, Q_2\} = \{C1, C2\}}
  ++ D is the derivation to use.

  baseRDEsys: (RF, RF, RF) -> Union(List RF, "failed")
  ++ baseRDEsys(f, g1, g2) returns fractions \spad{\{y_1, y_2\}} such that
  ++ \spad{\{y_1', y_2'\} + ((0, -f), (f, 0)) (y_1, y_2) = (g_1, g_2)}
++ if \spad{y_1,y_2} exist, "failed" otherwise.

Implementation ==> add

&+ \frac{\left( \varphi_1 - 2 \right) v - 4 \varphi_1 g \left( \varphi_1 - 2 \right)}{v - 4 \varphi_1 g} - 4 \varphi_1 \left( v - 4 \varphi_1 g \right) \left( \varphi_1 - 2 \right)
\end{align*}
\]

Type: Expression(Integer)
This package tries to find solutions of equations of type Expression(R).

This means expressions involving transcendental, exponential, logarithmic and nthRoot functions.

After trying to transform different kernels to one kernel by applying several rules, it calls zerosOf for the SparseUnivariatePolynomial in the remaining kernel.

For example the expression
\[ \sin(x) \cdot \cos(x) - 2 \]
will be transformed to
\[ -2 \tan(x/2)^4 - 2 \tan(x/2)^3 - 4 \tan(x/2)^2 + 2 \tan(x/2) - 2 \]
by using the function normalize and then to
\[ -2 \tan(x)^2 + \tan(x) - 2 \]
with help of subsTan. This function tries to express the given function in terms of \( \tan(x/2) \) to express in terms of \( \tan(x) \).

Other examples are the expressions
\[ \sqrt{x+1} + \sqrt{x+7} + 1 \]
\[ \sqrt{x} + 1 \]
\[ \text{solve}(1/2*v*v*cos(theta+phi)*cos(theta+phi)+g*l*cos(phi)=g*l,phi) \]
definingPolynomial \( \phi_0 \)
definingPolynomial \( \phi_1 \)

++ Date Created: Summer 1991
++ Date Last Changed: 9/91
++ Description:
++ This package tries to find solutions of equations of type Expression(R).
++ This means expressions involving transcendental, exponential, logarithmic
++ and nthRoot functions.
++ After trying to transform different kernels to one kernel by applying
++ several rules, it calls zerosOf for the SparseUnivariatePolynomial in
++ the remaining kernel.
++ For example the expression \spad{\sin(x)\cos(x)-2} will be transformed to
++ \spad{-2 \tan(x/2)^4 -2 \tan(x/2)^3 -4 \tan(x/2)^2 +2 \tan(x/2) -2}
++ by using the function normalize and then to
++ \spad{-2 \tan(x)^2 + \tan(x) -2}
++ with help of subsTan. This function tries to express the given function
++ in terms of \spad{\tan(x/2)} to express in terms of \spad{\tan(x)} .
++ Other examples are the expressions \spad{\sqrt{x+1}+\sqrt{x+7}+1} or
++ \spad{\sqrt{\sin(x)}+1}.

package SOLVESER TransSolvePackageService

TransSolvePackageService examples

This package finds the function func3 where func1 and func2 are given and func1 = func3(func2). If there is no solution then function func1 will be returned.
An example would be
\[
\text{func1} := 8\times 3 + 32\times 2 - 14\times X :: \text{EXPR INT}
\]
and
\[
\text{func2} := 2\times X :: \text{EXPR INT}
\]
convert them via univariate to \text{FRAC SUP EXPR INT} and then the solution is
\[
\text{func3} := X^3 + X^2 - X
\]
of type \text{FRAC SUP EXPR INT}

package TRIMAT TriangularMatrixOperations

This package provides functions that compute "fraction-free" inverses of upper and lower triangular matrices over an integral domain. By "fraction-free inverses" we mean the following: given a matrix $B$ with entries in $R$ and an element $d$ of $R$ such that $d \cdot \text{inv}(B)$ also has entries in $R$, we return $d \cdot \text{inv}(B)$. Thus, it is not necessary to pass to the quotient field in any of our computations.

++ Description:
++ Tools for constructing tubes around 3-dimensional parametric curves.

TubePlotTools(): Exports == Implementation where

I  ==> Integer
SF ==> DoubleFloat
L  ==> List
Pt  ==> Point SF

Exports ==> with
  point: (SF,SF,SF,SF) -> Pt
++ point(x1,x2,x3,c) creates and returns a point from the three
++ specified coordinates \spad{x1}, \spad{x2}, \spad{x3}, and also
++ a fourth coordinate, c, which is generally used to specify the
++ color of the point.
"*" : (SF,Pt) -> Pt
++ s * p returns a point whose coordinates are the scalar multiple
++ of the point p by the scalar s, preserving the color, or fourth
++ coordinate, of p.
"+" : (Pt,Pt) -> Pt
++ p + q computes and returns a point whose coordinates are the sums
++ of the coordinates of the two points \spad{p} and \spad{q}, using
++ the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.
"-" : (Pt,Pt) -> Pt
++ p - q computes and returns a point whose coordinates are the
++ differences of the coordinates of two points \spad{p} and \spad{q},
++ using the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.
dot : (Pt,Pt) -> SF
++ dot(p,q) computes the dot product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and returns
++ the resulting \spadtype{DoubleFloat}.
cross : (Pt,Pt) -> Pt
++ cross(p,q) computes the cross product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and keeping
++ the color of the first point p. The result is returned as a point.
unitVector: Pt -> Pt
++ unitVector(p) creates the unit vector of the point p and returns
++ the result as a point. Note that \spad{unitVector(p) = p/|p|}.
cosSinInfo: I -> L L SF
++ cosSinInfo(n) returns the list of lists of values for n, in the form
++ \spad{[[cos(n-1) a,sin(n-1) a],...,[cos 2 a,sin 2 a],[cos a,sin a]]}
++ where \spad{a = 2 pi/n}. Note that n should be greater than 2.
loopPoints: (Pt,Pt,Pt,SF,L L SF) -> L Pt
++ loopPoints(p,n,b,r,lls) creates and returns a list of points
++ which form the loop with radius r, around the center point
++ indicated by the point p, with the principal normal vector of
++ the space curve at point p given by the point(vector) n, and the
++ binormal vector given by the point(vector) b, and a list of lists,
++ lls, which is the \spadfun{cosSinInfo} of the number of points
++ defining the loop.

```lisp
)abbrev package TWOFACT TwoFactorize
++ Authors: P. Gianni, J.H. Davenport
++ Date Created: May 1990
++ Date Last Updated: March 1992
++ Description:
++ A basic package for the factorization of bivariate polynomials
++ over a finite field.
++ The functions here represent the base step for the multivariate factorizer.

TwoFactorize(F) : C == T
where
  F       : FiniteFieldCategory
  SUP     ==> SparseUnivariatePolynomial
  R       ==> SUP F
  P       ==> SUP R
  UPCF2   ==> UnivariatePolynomialCategoryFunctions2
```

---
C == with
  generalTwoFactor : (P) -> Factored P
  ++ generalTwoFactor(p) returns the factorisation of polynomial p,
  ++ a sparse univariate polynomial (sup) over a
  ++ sup over F.
  generalSqFr : (P) -> Factored P
  ++ generalSqFr(p) returns the square-free factorisation of polynomial p,
  ++ a sparse univariate polynomial (sup) over a
  ++ sup over F.
  twoFactor : (P,Integer) -> Factored P
  ++ twoFactor(p,n) returns the factorisation of polynomial p,
  ++ a sparse univariate polynomial (sup) over a
  ++ sup over F.
  ++ Also, p is assumed primitive and square-free and n is the
  ++ degree of the inner variable of p (maximum of the degrees
  ++ of the coefficients of p).

UnivariatePolynomialSquareFree examples
====================================================================

This package provides for square-free decomposition of univariate polynomials over arbitrary rings, i.e. a partial factorization such that each factor is a product of irreducibles with multiplicity one and the factors are pairwise relatively prime. If the ring has characteristic zero, the result is guaranteed to satisfy this condition. If the ring is an infinite ring of finite characteristic, then it may not be possible to decide when polynomials contain factors which are pth powers. In this case, the flag associated with that polynomial is set to "nil" (meaning that that polynomials are not guaranteed to be square-free).

vector_add_mul : (PA, PA, Integer, Integer, Integer, Integer) _
-> Void
++ vector_add_mul(v1, v2, m, n, c, p) sets v1(m), ..., 
++ v1(n) to corresponding entries in v1 + c*v2
++ modulo p.
mul_by_binomial : (PA, Integer, Integer) -> Void
++ mul_by_binomial(v, pt, p) treats v a polynomial
++ and multiplies in place this polynomial by binomial (x + pt).
++ Highest coefficient of product is ignored.
mul_by_binomial : (PA, Integer, Integer, Integer) -> Void
++ mul_by_binomial(v, deg, pt, p) treats v as
++ coefficients of polynomial of degree deg and
++ multiplies in place this polynomial by binomial (x + pt).
++ Highest coefficient of product is ignored.
mul_by_scalar : (PA, Integer, Integer, Integer) -> Void
++ mul_by_scalar(v, deg, c, p) treats v as
++ coefficients of polynomial of degree deg and
++ multiplies in place this polynomial by scalar c
mul : (PA, PA, Integer) -> PA
++ Polynomial multiplication.
truncated_multiplication : (PA, PA, Integer, Integer) -> PA
++ truncated_multiplication(x, y, d, p) computes
++ x*y truncated after degree d
truncated_mul_add : (PA, PA, PA, Integer, Integer) -> Void
++ truncated_mul_add(x, y, z, d, p) adds to z
++ the produce x*y truncated after degree d
pow : (PA, PositiveInteger, NonNegativeInteger, Integer) -> PA
++ pow(u, n, d, p) returns u^n truncated after degree d, except if
++ n=1, in which case u itself is returned
differentiate : (PA, Integer) -> PA
++ Polynomial differentiation.
differentiate : (PA, NonNegativeInteger, Integer) -> PA
++ Polynomial differentiation.
divide! : (PA, PA, PA, Integer) -> Void
++ Polynomial division.
remainder! : (PA, PA, Integer) -> Void
++ Polynomial remainder
vector_combination : (PA, Integer, PA, Integer, _
                   Integer, Integer, p : Integer) -> Void
    ++ vector_combination(v1, c1, v2, c2, n, delta, p) replaces
    ++ first n + 1 entries of v1 by corresponding entries of
    ++ c1*v1+c2*x^delta*v2 mod p.
to_mod_pa : (SparseUnivariatePolynomial Integer, Integer) -> PA
    ++ to_mod_pa(s, p) reduces coefficients of polynomial
    ++ s modulo prime p and converts the result to vector
gcd : (PA, PA, Integer) -> PA
    ++ gcd(v1, v2, p) computes monic gcd of v1 and v2 modulo p.
gcd : (PrimitiveArray PA, Integer, Integer, Integer) -> PA
    ++ gcd(a, lo, hi, p) computes gcd of elements
    ++ a(lo), a(lo+1), ..., a(hi).
lcm : (PrimitiveArray PA, Integer, Integer, Integer) -> PA
    ++ lcm(a, lo, hi, p) computes lcm of elements
    ++ a(lo), a(lo+1), ..., a(hi).
degree : PA -> Integer
    ++ degree(v) is degree of v treated as polynomial
extended_gcd : (PA, PA, Integer) -> List(PA)
    ++ extended_gcd(v1, v2, p) gives \[g, c1, c2\] such
    ++ that g is \spad{gcd(v1, v2, p)}, \spad{gcd = c1*v1 + c2*v2}
    ++ and degree(c1) < max(degree(v2) - degree(g), 0) and
    ++ degree(c2) < max(degree(v1) - degree(g), 1)
resultant : (PA, PA, Integer) -> Integer
    ++ resultant(v1, v2, p) computes resultant of v1 and v2
    ++ modulo p.

pointColorDefault : () -> PAL
++ pointColorDefault() returns the default color of points in a 2D
++ viewport.

pointColorDefault : PAL -> PAL
++ pointColorDefault(p) sets the default color of points in a 2D viewport
++ to the palette p.

lineColorDefault : () -> PAL
++ lineColorDefault() returns the default color of lines connecting
++ points in a 2D viewport.

lineColorDefault : PAL -> PAL
++ lineColorDefault(p) sets the default color of lines connecting points
++ in a 2D viewport to the palette p.

axesColorDefault : () -> PAL
++ axesColorDefault() returns the default color of the axes in a
++ 2D viewport.

axesColorDefault : PAL -> PAL
++ axesColorDefault(p) sets the default color of the axes in a 2D
++ viewport to the palette p.

unitsColorDefault : () -> PAL
++ unitsColorDefault() returns the default color of the unit ticks in
++ a 2D viewport.

unitsColorDefault : PAL -> PAL
++ unitsColorDefault(p) sets the default color of the unit ticks in
++ a 2D viewport to the palette p.

pointSizeDefault : () -> PI
++ pointSizeDefault() returns the default size of the points in
++ a 2D viewport.

pointSizeDefault : PI -> PI
++ pointSizeDefault(i) sets the default size of the points in a 2D
++ viewport to i.

viewPosDefault : () -> L NNI
++ viewPosDefault() returns the default x and y position of a
++ viewport window unless overridden explicitly, newly created
++ viewports will have this x and y coordinate.

viewPosDefault : L NNI -> L NNI
++ viewPosDefault([x,y]) sets the default x and y position of a
++ viewport window unless overridden explicitly, newly created
++ viewports will have the x and y coordinates x, y.

viewSizeDefault : () -> L PI
++ viewSizeDefault() returns the default viewport width and height.

viewSizeDefault : L PI -> L PI
++ viewSizeDefault([w,h]) sets the default viewport width to w and height
++ to h.

viewDefaults : () -> Void
++ viewDefaults() resets all the default graphics settings.

viewWriteDefault : () -> L S
++ viewWriteDefault() returns the list of things to write in a viewport
++ data file; a viewalone file is always generated.

viewWriteDefault : L S -> L S
++ viewWriteDefault(l) sets the default list of things to write in a
++ viewport data file to the strings in l; a viewalone file is always
++ generated.

viewWriteAvailable : () -> L S
++ viewWriteAvailable() returns a list of available methods for writing,
++ such as BITMAP, POSTSCRIPT, etc.
var1StepsDefault : () -> PI
++ var1StepsDefault() is the current setting for the number of steps to
++ take when creating a 3D mesh in the direction of the first defined
++ free variable (a free variable is considered defined when its
++ range is specified (e.g. x=0..10)).

var2StepsDefault : () -> PI
++ var2StepsDefault() is the current setting for the number of steps to
++ take when creating a 3D mesh in the direction of the first defined
++ free variable (a free variable is considered defined when its
++ range is specified (e.g. x=0..10)).

var1StepsDefault : PI -> PI
++ var1StepsDefault(i) sets the number of steps to take when creating a
++ 3D mesh in the direction of the first defined free variable to i
++ (a free variable is considered defined when its range is specified
++ (e.g. x=0..10)).

var2StepsDefault : PI -> PI
++ var2StepsDefault(i) sets the number of steps to take when creating a
++ 3D mesh in the direction of the first defined free variable to i
++ (a free variable is considered defined when its range is specified
++ (e.g. x=0..10)).

tubePointsDefault : PI -> PI
++ tubePointsDefault(i) sets the number of points to use when creating
++ the circle to be used in creating a 3D tube plot to i.

tubePointsDefault : () -> PI
++ tubePointsDefault() returns the number of points to be used when
++ creating the circle to be used in creating a 3D tube plot.

tubeRadiusDefault : Float -> SF -- current tube.spad asks for SF
++ tubeRadiusDefault(r) sets the default radius for a 3D tube plot to r.

tubeRadiusDefault : () -> SF
++ tubeRadiusDefault() returns the radius used for a 3D tube plot.

integralBasis() returns a record
++ \spad{integralBasis()} containing information regarding
++ the integral closure of R in the quotient field of F, where
++ F is a framed algebra with R-module basis \spad{w1, w2, ..., wn}.
++ If \spad{basis} is the matrix \spad{((aij, i = 1..n, j = 1..n))}, then
++ the \spad{i}th element of the integral basis is
++ \spad{vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
++ \spad{i}th row of \spad{basis} contains the coordinates of the
++ \spad{i}th basis vector. Similarly, the \spad{i}th row of the
++ matrix \spad{basisInv} contains the coordinates of \spad{wi} with
++ respect to the basis \spad{w1, ..., wn}: if \spad{basisInv} is the
++ matrix \spad{(bij, i = 1..n, j = 1..n)}, then
++ \spad{wi = sum(bij * vj, j = 1..n)}.

localIntegralBasis(p) returns a record
++ \spad{localIntegralBasis(p)} containing information regarding
++ the local integral closure of R at the prime \spad{p} in the quotient
++ field of F, where F is a framed algebra with R-module basis
++ \spad{w1, w2, ..., wn}.
++ If \texttt{basis} is the matrix \texttt{(aij, i = 1..n, j = 1..n)}, then
++ the \texttt{i}th element of the local integral basis is
++ \texttt{vi} = \left(1/basisDen\right) \times \sum(a_{ij} \times w_j, j = 1..n), i.e. the
++ \texttt{i}th row of \texttt{basis} contains the coordinates of the
++ \texttt{i}th basis vector. Similarly, the \texttt{i}th row of the
++ matrix \texttt{basisInv} contains the coordinates of \texttt{vi} with
++ respect to the basis \texttt{v1,...,vn}: if \texttt{basisInv} is the
++ matrix \texttt{(bij, i = 1..n, j = 1..n)}, then
++ \texttt{wi} = \sum(b_{ij} \times v_j, j = 1..n).

Type: List(List(RealClosure(Fraction(Integer))))

lpr2 := positiveSolve(lf)$pack

Type: PositiveInteger

lpr2 := positiveSolve(lf)$pack

Type: List(List(RealClosure(Fraction(Integer))))
A package for computing symbolically the complex and real roots of zero-dimensional algebraic systems over the integer or rational numbers. Complex roots are given by means of univariate representations of irreducible regular chains. Real roots are given by means of tuples of coordinates lying in the RealClosure of the coefficient ring.

This constructor takes three arguments. The first one R is the coefficient ring. The second one ls is the list of variables involved in the systems to solve. The third one must be concat(ls,s) where s is an additional symbol used for the univariate representations.

WARNING. The third argument is not checked.

All operations are based on triangular decompositions. The default is to compute these decompositions directly from the input system by using the RegularChain domain constructor.

The lexTriangular algorithm can also be used for computing these decompositions (see LexTriangularPackage package constructor).

For that purpose, the operations univariateSolve, realSolve and positiveSolve admit an optional argument.

The ZeroDimensionalSolvePackage package constructor provides operations for computing symbolically the complex or real roots of zero-dimensional algebraic systems.

The package provides no multiplicity information (i.e. some returned
roots may be double or higher) but only distinct roots are returned.

Complex roots are given by means of univariate representations of irreducible regular chains. These representations are computed by the univariateSolve operation (by calling the InternalRationalUnivariateRepresentationPackage package constructor which does the job).

Real roots are given by means of tuples of coordinates lying in the RealClosure of the coefficient ring. They are computed by the realSolve and positiveSolve operations. The former computes all the solutions of the input system with real coordinates whereas the later concentrate on the solutions with (strictly) positive coordinates. In both cases, the computations are performed by the RealClosure constructor.

Both computations of complex roots and real roots rely on triangular decompositions. These decompositions can be computed in two different ways. First, by applying the zeroSetSplit operation from the REGSET domain constructor. In that case, no Groebner bases are computed. This strategy is used by default. Secondly, by applying the zeroSetSplit from LEXTRIPK. To use this later strategy with the operations univariateSolve, realSolve and positiveSolve one just needs to use an extra boolean argument.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

The ZeroDimensionalSolvePackage constructor takes three arguments. The first one $R$ is the coefficient ring; it must belong to the categories OrderedRing, EuclideanDomain, CharacteristicZero and RealConstant. This means essentially that $R$ is Integer or Fraction(Integer). The second argument $ls$ is the list of variables involved in the systems to solve. The third one MUST BE concat($ls$, $s$) where $s$ is an additional symbol used for the univariate representations. The abbreviation for ZeroDimensionalSolvePackage is ZDSOLVE.

We illustrate now how to use the constructor ZDSOLVE by two examples: the Arnborg and Lazard system and the L-3 system (Aubry and Moreno Maza). Note that the use of this package is also demonstrated in the example of the LexTriangularPackage constructor.

Define the coefficient ring.

R := Integer
    Integer
    Type: Domain

Define the lists of variables:

ls : List Symbol := [x,y,z,t]
[x,y,z,t]  
Type: List Symbol

and:

ls2 : List Symbol := [x,y,z,t,new()$Symbol]  
[x,y,z,t,%A]  
Type: List Symbol

Call the package:

pack := ZDSOLVE(R,ls,ls2)  
ZeroDimensionalSolvePackage(Integer,[x,y,z,t],[x,y,z,t,%A])  
Type: Domain

Define a polynomial system (Arnborg-Lazard)

p1 := x**2*y*z + x*y**2*z + x*y*z**2 + x*y*z + x*y + x*z + y*z  
2 2 2  
(x y + (x + x + 1)y + x)z + x y  
Type: Polynomial Integer

p2 := x**2*y**2*z + x*y**2*z**2 + x**2*y*z + x*y*z + y*z + x + z  
2 2 2 2 2  
(x y + (x + x + 1)y + 1)z + x  
Type: Polynomial Integer

p3 := x**2*y**2*z**2 + x**2*y**2*z + x*y**2*z + x*y*z + x*z + z + 1  
2 2 2 2 2  
((x + x)y + x y + x + 1)z + 1  
Type: Polynomial Integer

lp := [p1, p2, p3]  
2 2 2  
(x y + (x y + (x + x + 1)y + x)z + x y,  
2 2 2 2  
(x y + (x + x + 1)y + 1)z + x,  
2 2 2 2  
((x + x)y + x y + x + 1)z + 1]  
Type: List Polynomial Integer

Note that these polynomials do not involve the variable t; we will use it in the second example.

First compute a decomposition into regular chains (i.e. regular triangular sets).

triangSolve(lp)$pack  
[
  
}
We can see easily from this decomposition (consisting of a single regular chain) that the input system has 20 complex roots.

Then we compute a univariate representation of this regular chain.

```
univariateSolve(lp)$pack
[[(z - 2z)y + (- z - z - 2z - 1)y - z - z + 1)x + z - 1]
```

Type: List RegularChain(Integer, [x, y, z, t])
We see that the zeros of our regular chain are split into three components. This is due to the use of univariate polynomial factorization.

Each of these components consist of two parts. The first one is an irreducible univariate polynomial $p(\alpha)$ which defines a simple algebraic extension of the field of fractions of $R$. The second one consists of multivariate polynomials $\text{pol1}(x,\%A)$, $\text{pol2}(y,\%A)$ and $\text{pol3}(z,\%A)$. Each of these polynomials involve two variables: one is an indeterminate $x$, $y$ or $z$ of the input system $lp$ and the other is $\%A$ which represents any root of $p(\alpha)$. Recall that this $\%A$ is the last element of the third parameter of ZDSOLVE. Thus any complex root $\alpha$ of $p(\alpha)$ leads to a solution of the input system $lp$ by replacing $\%A$ by this $\alpha$ in $\text{pol1}(x,\%A)$, $\text{pol2}(y,\%A)$ and $\text{pol3}(z,\%A)$. Note that the polynomials $\text{pol1}(x,\%A)$, $\text{pol2}(y,\%A)$ and $\text{pol3}(z,\%A)$ have degree one w.r.t. $x$, $y$ or $z$ respectively. This is always the case for all
univariate representations. Hence the operation univariateSolve replaces a system of multivariate polynomials by a list of univariate polynomials, what justifies its name. Another example of univariate representations illustrates the LexTriangularPackage package constructor.

We now compute the solutions with real coordinates:

</tbody>
</table>
The number of real solutions for the input system is:

```plaintext
# lr
```
Each of these real solutions is given by a list of elements in RealClosure(R). In these 8 lists, the first element is a value of z, the second of y and the last of x. This is logical since by setting the list of variables of the package to [x,y,z,t] we mean that the elimination ordering on the variables is t < z < y < x. Note that each system treated by the ZDSOLVE package constructor needs only to be zero-dimensional w.r.t. the variables involved in the system it-self and not necessarily w.r.t. all the variables used to define the package.

We can approximate these real numbers as follows. This computation takes between 30 sec. and 5 min, depending on your machine.

```
[ approximate(r,1/1000000) for r in point ] for point in lr ]
```

```

1706396253618176]
We can also concentrate on the solutions with real (strictly) positive coordinates:

```
lpr := positiveSolve(lp)$pack
```

Type: List List RealClosure Fraction Integer

```
We can also concentrate on the solutions with real (strictly) positive coordinates:
```

```
lpr := positiveSolve(lp)$pack
```

Type: List List RealClosure Fraction Integer
Thus we have checked that the input system has no solution with strictly positive coordinates.

Let us define another polynomial system (L-3).

\[
\begin{align*}
f_0 & := x^3 + y + z + t - 1 \\
& \quad z + y + x + t - 1 \\
& \quad \text{Type: Polynomial Integer}
\end{align*}
\]

\[
\begin{align*}
f_1 & := x + y^3 + z + t - 1 \\
& \quad z + y + x + t - 1 \\
& \quad \text{Type: Polynomial Integer}
\end{align*}
\]

\[
\begin{align*}
f_2 & := x + y + z^3 + t - 1 \\
& \quad z + y + x + t - 1 \\
& \quad \text{Type: Polynomial Integer}
\end{align*}
\]

\[
\begin{align*}
f_3 & := x + y + z + t^3 - 1 \\
& \quad z + y + x + t - 1 \\
& \quad \text{Type: Polynomial Integer}
\end{align*}
\]

\[
\begin{align*}
lf := [f_0, f_1, f_2, f_3] \\
& \quad \text{3 3 3 3} \\
& \quad [z + y + x + t - 1, z + y + x + t - 1, z + y + x + t - 1, z + y + x + t - 1] \\
& \quad \text{Type: List Polynomial Integer}
\end{align*}
\]

First compute a decomposition into regular chains (i.e. regular triangular sets).

\[
\begin{align*}
lts := \text{triangSolve}(lf)\text{pack} \\
& \quad \text{3} \\

The number of real solutions for the input system is:

```
#l2
27
```

Type: PositiveInteger

Another example of computation of real solutions illustrates the LexTriangularPackage package constructor.

We concentrate now on the solutions with real (strictly) positive
coordinates:

\[
lpr2 := \text{positiveSolve(1f)$pack} \\
\begin{bmatrix}
1 & 3 & 1 & 1 & 3 & 1 & 1 & 3 & 1 \\
3 & 3 & 3 & 3 & 3 & 3 & 3 & 3 & 3 \\
\end{bmatrix}
\]

Type: List List RealClosure Fraction Integer

Finally, we approximate the coordinates of this point with 20 exact digits:

\[
\text{approximate(r,1/10**21)::Float for r in lpr2.1} \\
[0.32218535462608559291, 0.32218535462608559291, 0.32218535462608559291, 0.32218535462608559291]
\]

Type: List Float

— package ZDSOLVE ZeroDimensionalSolvePackage —

)abbrev package ZDSOLVE ZeroDimensionalSolvePackage  
++ Author: Marc Moreno Maza  
++ Date Created: 23/01/1999  
++ Date Last Updated: 08/02/1999  
++ Description:  
++ A package for computing symbolically the complex and real roots of
++ zero-dimensional algebraic systems over the integer or rational
++ numbers. Complex roots are given by means of univariate representations
++ of irreducible regular chains. Real roots are given by means of tuples
++ of coordinates lying in the \spadtype{RealClosure} of the coefficient ring.
++ This constructor takes three arguments. The first one \spad{R} is the
++ coefficient ring. The second one \spad{ls} is the list of variables
++ involved in the systems to solve. The third one must be \spad{concat(ls,s)}
++ where \spad{s} is an additional symbol used for the univariate
++ representations.
++ WARNING. The third argument is not checked.
++ All operations are based on triangular decompositions.
++ The default is to compute these decompositions directly from the input
++ system by using the \spadtype{RegularChain} domain constructor.
++ The lexTriangular algorithm can also be used for computing these
++ decompositions (see \spadtype{LexTriangularPackage} package constructor).
++ For that purpose, the operations univariateSolve, realSolve and
++ positiveSolve admit an optional argument.

triangSolve: (LP,B,B) -> List RegularChain(R,ls)
++ \spad{triangSolve(lp,info?,lextri?)} decomposes the variety
++ associated with \axiom{lp} into regular chains.
++ Thus a point belongs to this variety iff it is a regular
++ zero of a regular set in in the output.
++ Note that \axiom{lp} needs to generate a zero-dimensional ideal.
++ If \axiom{lp} is not zero-dimensional then the result is only
++ a decomposition of its zero-set in the sense of the closure
++ (w.r.t. Zarisky topology).
++ Moreover, if \axiom{info?} is \axiom{true} then some information is
++ displayed during the computations.
++ See zeroSetSplit from RegularTriangularSetCategory(lp,true,info?).
++ If \axiom{lextri?} is \axiom{true} then the lexTriangular algorithm
++ is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly from
++ the input
++ system by using the zeroSetSplit from RegularChain

triangSolve: (LP,B) -> List RegularChain(R,ls)
++ \spad{triangSolve(lp,info?)} returns the same as
++ \spad{triangSolve(lp,false)}

triangSolve: LP -> List RegularChain(R,ls)
++ \spad{triangSolve(lp)} returns the same as
++ \spad{triangSolve(lp,false,false)}

univariateSolve: RegularChain(R,ls) -> _
++ \spad{univariateSolve(ts)} returns a univariate representation
++ of \axiom{ts}.
++ See rur from RationalUnivariateRepresentationPackage(lp,true).

univariateSolve: (LP,B,B,B) -> List RUR
++ \spad{univariateSolve(lp,info?,check?,lextri?)} returns a univariate
++ representation of the variety associated with \axiom{lp}.
++ Moreover, if \axiom{info?} is \axiom{true} then some information is
++ displayed during the decomposition into regular chains.
++ If \axiom{check?} is \axiom{true} then the result is checked.
++ See rur from RationalUnivariateRepresentationPackage(lp,true).
++ If \axiom{lextri?} is \axiom{true} then the lexTriangular
++ algorithm is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly
++ from the input
++ system by using the zeroSetSplit from RegularChain

univariateSolve: (LP,B,B) -> List RUR
++ \spad{univariateSolve(lp,info?,check?)} returns the same as
++ \spad{univariateSolve(lp,info?,check?,false)}.

univariateSolve: (LP,B) -> List RUR
univariateSolve: LP -> List RUR
++ \spad{univariateSolve(lp)} returns the same as
++ \spad{univariateSolve(lp,false,false)}.
realSolve: RegularChain(R,ls) -> List REALSOL
++ \spad{realSolve(ts)} returns the set of the points in the regular
++ zero set of \spad{ts} whose coordinates are all real.
++ the ordering of the indeterminates is reversed w.r.t. \spad{ls}.
realSolve: (LP,B,B,B) -> List REALSOL
++ \spad{realSolve(ts,info?,check?,lextri?)} returns the set of the
++ points in the variety associated with \spad{lp} whose coordinates
++ are all real.
++ Moreover, if \spad{info?} is \spad{true} then some information is
++ displayed during decomposition into regular chains.
++ If \spad{check?} is \spad{true} then the result is checked.
++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm
++ is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly from
++ the input
++ system by using the zeroSetSplit from \spadtype{RegularChain}.
++ WARNING. For each set of coordinates given by
++ \spad{realSolve(ts,info?,check?,lextri?)}
++ the ordering of the indeterminates is reversed w.r.t. \spad{ls}.
realSolve: (LP,B,B) -> List REALSOL
++ \spad{realSolve(ts,info?,check?)} returns the same as
++ \spad{realSolve(ts,info?,check?,false)}.
realSolve: LP -> List REALSOL
++ \spad{realSolve(lp)} returns the same as
++ \spad{realSolve(ts,false,false,false)}.
positiveSolve: RegularChain(R,ls) -> List REALSOL
++ \spad{positiveSolve(ts)} returns the points of the regular
++ set of \spad{ts} with (real) strictly positive coordinates.
positiveSolve: (LP,B,B) -> List REALSOL
++ \spad{positiveSolve(lp,info?,lextri?)} returns the set of the points
++ in the variety associated with \spad{lp} whose coordinates are
++ (real) strictly positive.
++ Moreover, if \spad{info?} is \spad{true} then some information is
++ displayed during decomposition into regular chains.
++ If \spad{lextri?} is \spad{true} then the lexTriangular
++ algorithm is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly
++ from the input
++ system by using the zeroSetSplit from \spadtype{RegularChain}.
++ WARNING. For each set of coordinates given by
++ \spad{positiveSolve(lp,info?,lextri?)}
++ the ordering of the indeterminates is reversed w.r.t. \spad{ls}.
positiveSolve: (LP,B) -> List REALSOL
++ \spad{positiveSolve(lp)} returns the same as
++ \spad{positiveSolve(lp,info?,false)}.
positiveSolve: LP -> List REALSOL
++ \spad{positiveSolve(lp)} returns the same as
++ \spad{positiveSolve(lp,false,false)}.

squareFree: (TS) -> List ST
++ \spad{squareFree(ts)} returns the square-free factorization
++ of \spad{ts}. Moreover, each factor is a Lazard triangular set
++ and the decomposition
++ is a Kalkbrener split of \spad{ts}, which is enough here for
++ the matter of solving zero-dimensional algebraic systems.
++ WARNING. \spad{ts} is not checked to be zero-dimensional.
convert: Q -> Q2
++ \spad{convert(q)} converts \spad{q}.
convert: P -> PRC
++ \spad{convert(p)} converts \spad{p}.
convert: Q2 -> PRC
++ \spad{convert(q)} converts \spad{q}.
convert: U -> URC
++ \spad{convert(u)} converts \spad{u}.
convert: ST -> List Q2
++ \spad{convert(st)} returns the members of \spad{st}.
